Buna SS	BC	IG	Co-polymer with styrene; more styrene than Buna S
Duprene *	C	DP	Now called Neoprene
Ethanite	PS	BC	Similar to Thiokol A
Flamenol	PV	GE	.....
Ker	B	S	.....
Korogel	PV	BFG	Highly plasticized Koroseal
Koroseal	PV	BFG	.....
Levulkan *	BC	IG	Now called Buna SS
Methyl rubber B	DB	B	Sodium used as catalyst
Methyl rubber H	DB	B	Cold polymerization
Methyl rubber W	DB	B	Hot polymerization
Neoprene	C	DP	.....
Mustone	C	UI	.....
Oppanol	IB	IG	.....
Perbunan	BC	IG	Co-polymer with acrylonitrile
Perbunan Extra	BC	IG	Higher nitrile content than Perbunan
Perduren	PS	IG	.....
Resinit *	PS	SR	.....
SKA	B	SR	From petroleum
SKB	B	SR	From alcohol
Sovoprene	C	SR	.....
Thiokol	PS	TC	.....
Thionite	PS	J	.....
Vistanex	IB	SO	.....
Vulcaplas	PS	IC	.....

*This term now commercially obsolete.

CHEMICAL STRUCTURES OF SYNTHETIC RUBBERS

Compound	Monomer	Polymer	Examples
Simple polymers:			
1,3-Butadiene	$CH_2{:}CH{\cdot}CH{:}CH_2$	$—CH_2{\cdot}CH{:}CH{\cdot}CH_2—$	Buna 85 and 115; SKA; SKB; Ker
2-Methyl-1,3-butadiene (isoprene)	$CH_2{:}C(CH_3)CH{:}CH_2$	$—CH_2{\cdot}C(CH_3){:}CH{\cdot}CH_2—$	Natural rubber
2,3-Dimethyl-1,3-butadiene	$CH_2{:}C(CH_3){\cdot}C(CH_3){:}CH_2$	$—CH_2{\cdot}C(CH_3){:}C(CH_3){\cdot}CH_2—$	Methyl rubber
2-Chloro-1,3-butadiene (chloroprene)	$CH_2{:}C(Cl){\cdot}CH{:}CH_2$	$—CH_2{\cdot}C(Cl){:}CH{\cdot}CH_2—$	Neoprene; Sovprene; Mustone
2-Methyl-1-propene (isobutene)	$(CH_3)_2C{:}CH_2$	$—C(CH_3)_2{\cdot}CH_2—$	Vistanex; Oppanol
Chloroethene (vinyl chloride)	$ClCH{:}CH_2$	$—CHCl{\cdot}CH_2—$	Plasticized materials; Koroseal; Korogel; Flamenol
Co-polymers:			
Butadiene + styrene	$CH_2{:}CH{\cdot}CH{:}CH_2 + C_6H_5CH{:}CH_2$	$—CH_2{\cdot}CH{:}CH{\cdot}(CH_2)_2{\cdot}CH(C_6H_5)—$	Buna S and Buna SS
Butadiene + acrylonitrile	$CH_2{:}CH{\cdot}CH{:}CH_2 + CH_2{:}CH{\cdot}CN$	$—CH_2{\cdot}CH{:}CH{\cdot}(CH_2)_2{\cdot}CH(CN)—$	Perbunan and Perbunan Extra
Polysulfides:			
Ethylene chloride + sodium tetrasulfide	$ClCH_2{\cdot}CH_2Cl + Na_2S_4$	$—CH_2{\cdot}CH_2{\cdot}S(:S){\cdot}S(:S)—$	Thiokol A
Dichloroethyl ether + sodium tetrasulfide	$(ClCH_2{\cdot}CH_2)_2O + Na_2S_4$	$—CH_2{\cdot}CH_2{\cdot}O{\cdot}CH_2{\cdot}CH_2{\cdot}S(:S){\cdot}S(:S)—$	Thiokol B; Perduren G

ELECTRICAL PROPERTIES OF SYNTHETIC RUBBERS

Abbreviations used in the table:
E, dielectric constant.
L, conductivity in mho/cm.
PF, power factor.

Name	*E*	*L*	*PF*
Neoprene[d,e]	7.5†	1×10^{-12}	300×10^{-4}†
Perbunan[e]	*ca.*15	*ca.* 1×10^{-7}	.....
Buna 85; 115, and S	2.9*	*ca.* 1×10^{-14}	7×10^{-4}*
Thiokol	4.6	.....	.....
Vistanex	2.3†§	$<20 \times 10^{-18}$	1.5×10^{-4}† 3.4×10^{-4}§
Vinyl chloride[a]	3.3†	0.1×10^{-12}	.....
Vinyl chloride[b]	5.7†	2.8×10^{-12}	.....
Vinyl chloride[c]	9.7†	323×10^{-12}	.....

(a) With 0% tricresyl phosphate as plasticizer.
(b) With 30% tricresyl phosphate as plasticizer.
(c) With 60% tricresyl phosphate as plasticizer.
(d) With only enough added ingredients to insure proper vulcanization.
(e) Polar groups—chlorine in Neoprene and Koroseal, nitrile in Perbunan—result in relatively high values of conductivity and dielectric constant. This is advantageous in the dissipation of undesired static charges.
* At 50 c/s.
† At 1000 c/s.
§ At 100,000 c/s.

PHYSICAL PROPERTIES OF SYNTHETIC RUBBERS

Abbreviations used in the table:
D, density, g./cc. at 20° to 25°C.
n_D^t, index of refraction at t°C. and D line wave length.
T, tensile strength in kg./sq. cm.
E, elongation in %.

(c) With 60% plasticizer.
† Not vulcanizable.

SWELLING OF VULCANIZED SYNTHETIC RUBBERS IN LIQUIDS

The first eight liquids are petroleum products, in the handling of which synthetic rubber has been found particularly useful. Unfortunately, the common names used for the liquids are insufficient to describe their chemical compositions, which may vary widely with place of origin and subsequent treatment. Since the swelling is determined largely by the chemical composition of the liquid, such a wide variation of values is obtained that the figures quoted for these products are less significant than those for the others. Neoprene, for example, may swell in different lubricating oils at 100°C. as much as 120% or as little as 12%. Correlation is found with a figure

which represents to some extent the ratio of aliphatic to aromatic constituents in the oil. Usually the tensile strength of a synthetic rubber shows less impairment than that of natural rubber, even when the amounts of swelling are not widely different. Synthetic compounds can be made which are greatly superior to natural rubber in that there is much less extraction of soluble material by liquids in contact with them.

The table below gives the volume increase, in %, after immersion for 8 weeks at room temperature.

Liquid	Natural rubber	Neoprene	Perbunan	Perbunan Extra	Thiokol A	Thiokol D	Thiokol DX, F

PERMEABILITY OF SYNTHETIC RUBBERS

Buna S, Buna 85, and Buna 115 possess about the same permeabilities to air as natural rubber does, but Perbunan shows a permeability less than half as large.

The table below gives the diffusion of water in terms of grams of water vapor passing through 1 sq. cm. of material 1 cm. thick in one hour under a differential pressure of 1 mm. of mercury; i.e., $g \cdot hr^{-1} \cdot cm \cdot cm^{-2} \cdot (mm\ of\ Hg)^{-1}$.

The permeability of hydrogen is given in terms of cubic centimeters per minute passing through a membrane 1 cm. thick and 1 sq. cm. in area, when it separates air at atmospheric pressure from the gas at a pressure of 30 mm. of water above atmospheric; i.e., $cm^3 \cdot min^{-1} \cdot cm \cdot cm^{-2}$.

PLASTICS

From information contained in *Plastics in the National Defense*, by Robert J. Moore, Bakelite Corporation; *Trans. Am. Inst. Chem. Engrs.* 37, *521 (1941)*. Reprinted with permission.

Plastics are amorphous substances and, unlike crystalline compounds, do not possess physical properties which can be regarded as true constants. Moreover, many commercial plastics are variable mixtures of substances with formulations made to meet certain conditions of use. It is for these reasons that tables of physical properties can not be presented in the same manner as tables of physical properties of crystalline compounds. For concise information as to composition, properties and trade names reference can be made to "*Modern Plastics Catalog*," published by Breskin Publishing Corp., 122 E. 42nd St., New York.

To illustrate the kinds of properties generally required of a plastic material and the numerical values of these properties the following list is given for a widely used "high impact" phenolic molding material. Determinations of the values were made according to *A.S.T.M. Standard Tests.*

Specific gravity	1.37–1.40
Weight per cubic inch	0.79–0.81 oz. (22.4–22.9 g.)
Tensile strength	6800–7200
Compressive strength	20,000–30,000
Impact strength*	25–30 ft.-lbs. for an inch sq.
Flexural strength (transverse)	10,000–13,000
Modulus of elasticity (by flexure)	$0.70–1.00 \times 10^6$
Distortion under heat (2.5 kgm. load)	130°C.
Specific heat	0.30–0.35
Thermal conductivity**	$3–4 \times 10^{-6}$
Coefficient of heat expansion	45×10^{-6}
Dielectric strength†	300–400
" " ‡	200–300
Volume resistivity at 30°C.	$0.5–1.0 \times 10^5$ megohms/cc.
Power factor (10^3 cycles)	0.08–0.20 (8%–20%)
" " (10^6 cycles)	0.05–0.10 (5%–10%)
Dielectric constant (10^3 cycles)	4.5–6.0
" " (10^6 cycles)	4.5–6.0
Water absorption#	*ca.* 1.0%
" " ##	*ca.* 3.3%
Standard colors	black, brown and tan
Colors made to order	a limited range

* *Energy to break test piece* $/bd^2$ where b = width, and d = thickness measured in the direction of force application.
** Calories per cm^2 per sec. per °C. per cm.
† Instantaneous 60 cycles.
‡ Step 60 cycles.
Disc 2 inches diameter by ¼ inch thick for 24 hrs.
Disc 2 inches diameter by ¼ inch thick for 144 hrs.

EXPLANATION OF TABLES I AND II

In the two tables which follow, the plastics have been classified into 13 types and designated by the letters from *A* to *M*.

TYPES OF PLASTICS

A Phenolic, general purpose
B Phenolic, low-loss
C Phenolic, heat-resistant
D Phenolic, acid- and alkali-resistant
E Phenolic, shock-resistant
F Phenolic, transparent
G Urea
H Polystyrene
I Cellulose acetate
J Aceto-butyrate
K Ethyl cellulose
L Methyl methacrylate
M Vinyl (no filler)

The values in the following two tables are all relative values and make possible a comparison between types. Thus, from Table I a comparison of type *B* with type *F* for the property of toughness is to be interpreted in the sense that *F* shows 4 times the toughness as does *B*.

In Table II, relative values are given with *number one as the best* for the given condition. Thus, type *J* is rated *1* (i.e., *first* or *best*) for toughness whereas type *B* (11) is *eleventh* or *poorest* of all the types. Table II is intended to assist a designer in making a selection of material to meet certain conditions. *Example*—Which plastic is most suitable for an automobile distributor head? *Answer*—Toughness is a property to be desired and from the table it is found that *E* is the most suitable thermoplastic material. Flexural and tensile strength are not highly important nor is the matter of color. Cold flow must be considered. Here all the phenolic materials appear to be suitable. In the next group of properties only water resistance need be considered and here *H* is first, *M* is second, and *B* and *C* are tied for third place. In the next group of properties are dimensional change on aging and heat resistance. For aging will be found the following types in their order of suitability: (1st) *C;* (2d) *B;* (3d) *H* and *M;* (4th) *A*. For heat resistance the order is: (1st) *C;* (2d) *A;* (3d) *B;* (4th) *J*. Of the remaining properties dielectric strength and moldability around inserts are the most important. For dielectric strength the order of suitability is: (1st) *H*, *K*, and *M;* (2d) *G;* (3d) *B*. For moldability around inserts the phenolics *A* to *F* have an advantage over all the others. Thus it is evident that, all properties considered, the phenolics *A* to *F* have an advantage over all the others. Which of the phenolics is to be selected is a matter of cost. The general-purpose material *A* is the cheapest not only in the price per pound but also because of its lower density. While *A* may not be the best material for the job yet it is amply suitable and therefore is commonly used in the manufacture of distributor heads.

TABLE I. PROPERTIES OF PLASTICS

Properties	Types of Plastics

* Charpy. ** Impact strength. † Recommended for dark shades only. # All shades possible.

§ Relative % decrease in height of ½ inch cube, 24 hrs., 120°F., 1000 lbs. load; values show minimum-maximum ranges according to formulations.

‡ Values are for continuous heat and show highest useful temperature rating; special formulations may vary ratings on permanently thermoplastic materials.

[a] The higher the rating the better the heat conduction.

[b] Immersion A.S.T.M.; values show minimum-maximum ranges of water absorption according to formulations. Of all the thermoplastics, the polystyrenes and the copolymer vinyls rank first in water resistance; *e.g.*, water absorption of copolymer vinyl is less than 0.1% for 24 hrs. immersion.

[c] *E*, excellent; *VG*, very good; *G*, good to other than strong oxidizing acids; *F*, fair; *P*, poor; *VP*, very poor.

[d] Weight per unit volume; values show minimum-maximum ranges according to formulations.

[e] A.S.T.M. ½ inch instantaneous; values show minimum-maximum ranges according to formulations.

[f] Assuming polystyrene, which shows the lowest loss, to have unit value. This rating is arbitrary since frequencies change relative losses.

[g] Assuming phenolic shock-resistant, which is the lowest, to have unit value and considering its excellent resistivity the ratings for the higher ones are fantastic. All are good insulators for direct current.

Anhydrone	Anhydrous magnesium perchlorate	$Mg(ClO_4)_2$
Animal oil	cf. Bone oil	.....
o-Anisidine	*o*-Methoxy-aniline	C_7H_9ON
Anthion	Potassium persulfate	$K_2S_2O_8$
Antichlor	Sodium thiosulfate	$Na_2S_2O_3 \cdot 5H_2O$
Antimonine	Antimony lactate	$Sb(C_3H_5O_3)_3$
Antimony (crude)	Antimony trisulfide	Sb_2S_3
Antimony black	Antimony trisulfide	Sb_2S_3
Antimony bloom	Antimony trioxide	Sb_2O_3
Antimony glance	Antimony trisulfide	Sb_2S_3
Antimony gray	Antimony trisulfide	Sb_2S_3
Antimony red Antimony vermilion	Antimony pentasulfide or antimony oxysulfide	Sb_2S_5 or $Sb_2S_3 + Sb_2O_3$
Antimony white	Antimony trioxide	Sb_2O_3
Antimony yellow	Basic lead antimonate	$PbO \cdot Sb_2O_5$
Ant oil (artificial)	Furfural	$C_4H_3O \cdot CHO$
Apple acid	Malic acid	$H_2C_4H_4O_5$
Aqua fortis	Nitric acid	HNO_3
Aqua regia	Mixture of nitric and hydrochloric acids	$HNO_3 + 3HCl$
Aquadag	Colloidal solution of graphite	.....
Arctic essence	Methyl chloride	CH_3Cl
Argatoxyl	Silver atoxylate	$NH_2C_6H_4 \cdot AsO \cdot AgO \cdot OH$
Argol	Impure potassium hydrogen tartrate	$KHC_4H_4O_6$
Armstrong and Wynne's acid	1-Naphthol-3-sulfonic acid	$C_{10}H_8O_4S$
Arnaudon's green	Chromic hydroxide combination with some acid as boric, phosphoric, etc.	.....
Arsenic glass	Arsenic trioxide	As_2O_3
Arsenic red (or orange)	Arsenic disulfide	As_2S_2
Ascarite	Sodium hydroxide deposited on inert material	NaOH
Atabrine	cf. Quinacrine hydrochloride	.....
Atoxyl	Sodium *p*-aminophenyl-arsonate	$NH_2C_6H_4AsO \cdot OH \cdot ONa$
Auricome	Hydrogen peroxide	H_2O_2
Auripigment	Arsenic trisulfide	As_2S_3
Aurora orange (or yellow)	Cadmium sulfide	CdS
Azure blue	cf. Cobalt blue	.....
Azure copper	cf. Copper carbonate blue	.....
B acid	1-Amino-8-naphthol-3, 5-disulfonic acid	$C_{10}H_9O_7NS_2$
Bakelite	Phenol-formaldehyde condensation resin	.....

TRADE NAMES OF CHEMICALS WITH SYNONYMS AND FORMULAS

Common or Trade Name	Chemical Synonym	Formula
Baking soda	Sodium hydrogen carbonate	$NaHCO_3$
Baldwin's phosphorus	Fused calcium nitrate	$Ca(NO_3)_2$
Ballistite	Smokeless powder	50% nitroglycerin and 50% collodion cotton
Barium white	Barium sulfate	$BaSO_4$
Barium yellow	Barium chromate	$BaCrO_4$
Baryta water	Barium hydroxide solution	$Ba(OH)_2$ + aq.
Baryta yellow	Barium chromate	$BaCrO_4$
Battery acid	Sulfuric acid	H_2SO_4
Battery manganese	Manganese dioxide	MnO_2
Beckton white	cf. Lithopone	.....
Bentonite	Impure aluminum silicate	.....
Benzine	Gasoline, petroleum ether	.....
Benzinoform	Carbon tetrachloride	CCl_4
Benzoline	cf. Naphtha, petroleum	.....
Bicarburetted hydrogen	Ethylene	C_2H_4
Bichrome	Potassium (or sodium) dichromate	K_2(or Na_2)Cr_2O_7
Bismuth white	Bismuth subnitrate or bismuth oxychloride	$BiONO_3 \cdot H_2O$ or BiOCl
Bismuth yellow	Bismuth chromate	$Bi_2(CrO_4)_3$
Bitter salt	Magnesium sulfate	$MgSO_4 \cdot 7H_2O$
Black antimony	Antimony trisulfide	Sb_2S_3
Black ash	Impure sodium carbonate	Na_2CO_3
Black flux	Mixture of potassium carbonate and carbon	K_2CO_3 and C
Black precipitate	Mercurous chloride	HgCl
Blanc de perle	Bismuth oxychloride	BiOCl
Blanc d'Espagne	Bismuth oxychloride	BiOCl
Blau gas	Blue gas	44% CH_4, 52% H_2
Bleaching powder	Calcium chloro-hypochlorite	CaClOCl
Blue copperas	Copper sulfate	$CuSO_4 \cdot 5H_2O$
Blue malachite	cf. Copper carbonate blue	.....
Blue salts	Nickel sulfate	$NiSO_4 \cdot 6H_2O$
Blue stone	Copper sulfate	$CuSO_4 \cdot 5H_2O$
Blue verdigris	Basic copper acetate	$Cu(C_2H_3O_2)_2 \cdot CuO$
Blue verditer	Basic copper carbonate	$2CuCO_3 \cdot Cu(OH)_2$
Blue vitriol	Copper sulfate	$CuSO_4 \cdot 5H_2O$
Boletic acid	Fumaric acid	$(CH \cdot CO_2H)_2$
Bone black	Animal charcoal	C
Bone oil	Mixture of pyrrole, pyridine, quinoline, fatty acids and nitriles, amines, and hydrocarbons from distillation of bones	.....
Boracic acid	Boric acid	H_3BO_3
Boroform	Acetylene tetrachloride	$(CHCl_2)_2$
Bremen blue	cf. Copper carbonate blue	.....
Bremen green	cf. Brunswick green	.....
Brimstone	Sulfur	S
Brunswick green	Basic copper carbonate	$Cu_2(OH)_2CO_3$
Burnt alum	Anhydrous potassium aluminum sulfate	$K_2Al_2(SO_4)_4$
Burnt lime	Calcium oxide	CaO
Burnt ochre	Ferric oxide	Fe_2O_3
Burnt ore	Ferric oxide	Fe_2O_3
Buttercup yellow	cf. Zinc yellow	.....

TRADE NAMES OF CHEMICALS WITH SYNONYMS AND FORMULAS

Common or Trade Name	Chemical Synonym	Formula
"Butter of"	Chloride of	.....
Butter of antimony	Antimony trichloride solution	$SbCl_3$ +aq.
Butyl glycol	Glycol monobutyl ether	$HOC_2H_4OC_4H_9$
C acid	2-Naphthol-4, 8-disulfonic acid	$C_{10}H_8O_7S_2$
Cadmium yellow	Cadmium sulfide	CdS
Calamine *	Zinc carbonate	$ZnCO_3$
Calcic liver of sulfur	Calcium sulfide	CaS
Calgon	Sodium hexametaphosphate	$(NaPO_3)_6$
Caliche	Impure sodium nitrate	$NaNO_3$
Calomel	Mercurous chloride	HgCl
Calx	Calcium oxide	CaO
Calx chlorinata	cf. Bleaching powder	.....
Canadol	cf. Naphtha, petroleum	.....
Canton's phosphorus	Calcium sulfide	CaS
Caoutchouc	Rubber	$(C_5H_8)_n$
Caput mortum	Ferric oxide, red	Fe_2O_3
Carbon chloride, Julin's	Hexachlorobenzene	C_6Cl_6
Carbon hexachloride	Hexachloroethane	C_2Cl_6
Carbonic acid	Carbon dioxide	CO_2
Carbonic anhydride	Carbon dioxide	CO_2
Carborundum	Silicon carbide	SiC
Carrene	Methylene chloride	CH_2Cl_2
Cassel's green	Barium manganate	$BaMnO_4$
"Caustic"	Hydroxide of	.....
Caustic alcohol	Sodium ethylate	C_2H_5ONa
Caustic antimony	Antimony trichloride	$SbCl_3$
Cellon	Acetylene tetrachloride	$(CHCl_2)_2$
Ceruse	Basic lead carbonate	$2PbCO_3 \cdot Pb(OH)_2$
Cerussa	cf. Ceruse	.....
Chalk	Calcium carbonate	$CaCO_3$
Charlton white	cf. Lithopone	.....
Chile niter	Sodium nitrate	$NaNO_3$
Chile saltpeter	cf. Saltpeter	.....
Chinacrin	cf. Atabrin	.....
Chinese blue	cf. Prussian blue	.....
Chinese red	Basic lead chromate	$PbCrO_4 \cdot PbO$
Chinese oxide	Zinc oxide	ZnO
Chinese vermilion	Mercuric sulfide (red)	HgS
Chinese white	Zinc oxide	ZnO
Chloralum	Aluminum chloride	$AlCl_3 \cdot 6H_2O$
Chloride of lime	cf. Bleaching powder	.....
Chloride of soda	Sodium hypochlorite solution	NaOCl +aq.
Chloro-H acid	1-Chloro-8-naphthol-3, 6-disulfonic acid	$C_{10}H_7O_7S_2Cl$
Chrome alum	Potassium chromium sulfate	$K_2Cr_2(SO_4)_4 \cdot 24H_2O$
Chrome green	Chromium oxide	Cr_2O_3
Chrome red	Basic lead chromate	$PbCrO_4 \cdot PbO$
Chrome yellow	Lead chromate	$PbCrO_4$
Chromic acid	Chromium trioxide	CrO_3
Cinnabar (artificial)	Mercuric sulfide (red)	HgS
Cinnabar, Austrian	cf. Chrome red	.....
Citron yellow	cf. Zinc yellow	.....
Cleve's α-acid	1-Naphthylamine-5-sulfonic acid	$C_{10}H_9O_3NS$
Cleve's β-acid	1-Naphthylamine-6-sulfonic acid	$C_{10}H_9O_3NS$

* Chiefly of British term; cf. also Table of Minerals.

TRADE NAMES OF CHEMICALS WITH SYNONYMS AND FORMULAS

Common or Trade Name	Chemical Synonym	Formula
Cleve's γ-acid	1-Naphthylamine-3-sulfonic acid	$C_{10}H_9O_3NS$
Cleve's δ-acid	1-Naphthylamine-7-sulfonic acid	$C_{10}H_9O_3NS$
Cleve's θ-acid	1-Naphthylamine-7-sulfonic acid	$C_{10}H_9O_3NS$
Cobalt black	Cobalt oxide, sesqui-	Co_2O_3
Cobalt blue	Oxides of cobalt and aluminum in varying proportions, or cobalt aluminate	.....
Cobalt green	Cobalt zincate	$CoZnO_2$
Cobalt violet	Cobaltous ammonium phosphate	$CoNH_4PO_4 \cdot H_2O$
Cobalt yellow	Potassium cobaltinitrite	$Co(NO_2)_3 \cdot 3KNO_2 \cdot 1.5H_2O$
Cobalt ultramarine	cf. Cobalt blue	.....
Colcothar	A red-brown ferric oxide obtained by heating ferrous sulfate	Fe_2O_3
Cologne yellow	Lead chromate	$PbCrO_4$
Common salt	Sodium chloride	NaCl
Copperas	Ferrous sulfate	$FeSO_4 \cdot 7H_2O$
Copper carbonate blue	Basic copper carbonate, composition variable	*ca.* $2CuCO_3 \cdot Cu(OH)_2$
Copper lasur	cf. Brunswick green	.....
Corrosive sublimate	Mercuric chloride	$HgCl_2$
Cosmetic bismuth	Bismuth oxychloride	BiOCl
Cream of tartar	Potassium hydrogen tartrate	$KHC_4H_4O_6$
Cresolin; Cresotal	Carbonate esters of cresols, guaiacol, etc.	.....
Crocus of antimony	Antimony sulfide, or a slag obtained in refining antimony, mainly sodium or potassium thioantimonite	Sb_2S_3, or Na_3SbS_3 or K_3SbS_3
Crocus of Mars (or Martis)	cf. Colcothar	.....
Crystal carbonate	Sodium carbonate (monohydrate)	$Na_2CO_3 \cdot H_2O$
Cubic nitre	Sodium nitrate	$NaNO_3$
Cupren	Acetylene polymer	$(C_2H_2)_n$ +0.2% to 0.3% Cu
Cupricin	Cuprous cyanide	$Cu_2(CN)_2$
Cystamine	cf. Hexamin	.....
Cystogen	cf. Hexamin	.....
Dahl's acid II	1-Naphthylamine-4, 6-disulfonic acid	$C_{10}H_9O_6NS_2$
Dahl's acid III	1-Naphthylamine-4, 7-disulfonic acid	$C_{10}H_9O_6NS_2$
de Haens salt	Mixture of sodium fluoride and antimony trifluoride	$NaF + SbF_3$
Dehydrite	Magnesium perchlorate	$Mg(ClO_4)_2$
Dehydro-thio-*p*-toluidine	1-(*p*-Aminophenyl)-3-methyl-benzothiazole	$C_{14}H_{12}N_2S$
Dental gas	Nitrous oxide	N_2O
Depurated tartar	Pure potassium hydrogen tartrate	$KHC_4H_4O_6$
Derby red	Basic lead chromate	$PbCrO_4 \cdot PbO$
Dermatol	Basic bismuth gallate	$Bi(OH)_2C_7H_5O_5$
Detonal	Diethylacetyl urethane	$(C_2H_5)_2CHCONHCO_2C_2H_5$
Dialozite	Manganese carbonate	$MnCO_3$
Diamine hydrate	Hydrazine hydrate	$(NH_2)_2 \cdot H_2O$
Diapthol	*o*-Hydroxyquinoline-*m*-sulfonic acid	$HOC_9H_5NSO_3H$
Diatol	Diethyl carbonate	$(C_2H_5O)_2CO$
Diazotizing salts	Sodium nitrite	$NaNO_2$
Dimethyl-gamma acid	2-Dimethylamino-8-naphthol-6-sulfonic acid	$C_{12}H_{13}O_4NS$

TRADE NAMES OF CHEMICALS WITH SYNONYMS AND FORMULAS

Common or Trade Name	Chemical Synonym	Formula
Diolin	Octadecanediol	$CH_3(CH_2)_5CHOH(CH_2)_{10}\cdot CH_2OH$
Dioxogen	cf. Bone oil	.....
Dippel's oil	cf. Bone oil	.....
Dipping acid	Sulfuric acid	H_2SO_4
Dissolvan CA or DN	Mixture of 60-80°C. boiling solvents for nitro- and acetyl-celluloses	.....
Disulfo acid E	1-Naphthol-3, 8-disulfonic acid	$C_{10}H_8O_7S_2$
Disulfo acid F	2-Naphthylamine-3, 7-disulfonic acid	$C_{10}H_7O_6NS_2$
Disulfuric acid	Fuming sulfuric acid	$H_2SO_4+SO_3$
Diuretic salt	Potassium acetate	$KC_2H_3O_2$
Dolomol	Magnesium stearate	$Mg(C_{18}H_{35}O_2)_2$
Dowicide	Various chlorophenols	ClC_6H_4OH
Dragonic acid	Anisic acid	$CH_3O\cdot C_6H_4\cdot CO_2H$
Dry ice	Solid carbon dioxide	CO_2
DTS	Dehydrothio-*p*-toluidine sulfonic acid	$C_{14}H_{12}O_3N_2S_2$
Dulcose	Dulcitol	$C_6H_8(OH)_6$
Dung salt	Sodium arsenate	Na_2HAsO_4
Dunging salt	Sodium silicate	$Na_2O\cdot 4SiO_2$
Duresco	cf. Lithopone	.....
Eau-de-Javelle	Potassium hypochlorite solution	KOCl+aq.
Eau-de-Labarraque	Sodium hypochlorite solution	NaOCl+aq.
Elayl	Ethylene	C_2H_4
Electrolon	Silicon carbide	SiC
Emerald green	cf. Paris green	.....
Emeraude green	cf. Guignet's green	.....
Enamel white	cf. Lithopone	.....
English salt	Ammonium carbonate	$(NH_4)_2CO_3$
English white	Calcium carbonate	$CaCO_3$
Epsilon acid or ϵ acid	1-Naphthylamine-3, 8-disulfonic acid	$C_{10}H_9O_6NS_2$
	1-Naphthol-3, 8-disulfonic acid	$C_{10}H_8O_7S_2$
	1, 8-Dihydroxy-naphthalene-3-sulfonic acid	$C_{10}H_8O_5S$
Erdmann's μ acid	1-Naphthylamine-6-sulfonic acid	$C_{10}H_9O_3NS$
Essential salt of lemon	Potassium hydrogen oxalate	KHC_2O_4
Etherin	Ethylene	C_2H_4
Ethiops mineral	Impure black mercuric sulfide	*ca.* 60% HgS+40% S
Ethocel	Ethyl cellulose	.....
Ethyl F acid	2-Ethylaminonaphthalene-7-sulfonic acid	$C_{12}H_{13}O_3NS$
Ethyl-gamma acid	2-Ethylamino-8-naphthol-6-sulfonic acid	$C_{12}H_{13}O_4NS$
Eunatrol	Sodium oleate	$C_{17}H_{33}CO_2Na$
Euonymit	Dulcitol	$C_6H_8(OH)_6$
Everitt's salt	Potassium ferrous ferrocyanide	$K_2Fe_2(CN)_6$
F acid	2-Naphthol-7-sulfonic acid	$C_{10}H_8O_4S$
	2-Naphthylamine-7-sulfonic acid	$C_{10}H_9O_3NS$
	2-Naphthylamine-3, 7-disulfonic acid	$C_{10}H_9O_6NS_2$
	2-Amino-7-naphthol-3-sulfonic acid	$C_{10}H_9O_4NS$
	2, 7-Dihydroxy-naphthalene-3-sulfonic acid	$C_{10}H_8O_5S$
Ferro prussiate	Any ferrocyanide, specifically potassium ferrocyanide	$K_4Fe(CN)_6$
Fischer's salt	Potassium cobaltic nitrite	$K_3Co(NO_2)_6\cdot 1.5H_2O$
Fischer's yellow	cf. Fischer's salt	.....

TRADE NAMES OF CHEMICALS WITH SYNONYMS AND FORMULAS

Common or Trade Name	Chemical Synonym	Formula
Fixed niter (nitre)	Potassium carbonate	K_2CO_3
Fixed white	Barium sulfate	$BaSO_4$
Flake white	Bismuth subnitrate, or (in paint) white lead	$BiONO_3 \cdot H_2O$ $2PbCO_3 \cdot Pb(OH)_2$
Flores martis	Ferric chloride	$FeCl_3 \cdot 6H_2O$
"Flowers of" a metal	Oxide of the metal	.....
Flowers of antimony	Antimony trioxide	Sb_2O_3
Flowers of bismuth	Bismuth trioxide	Bi_2O_3
Flowers of sulfur	Sublimed sulfur	S
Flowers of tin	Stannic oxide	SnO_2
Flowers of tin stone	Stannic oxide	SnO_2
Flowers of zinc	Zinc oxide	ZnO
Fluoremetic	Antimony sodium fluoride	$SbF_3 \cdot NaF$
Fluorol	Sodium fluoride	NaF
Formalin	40% Formaldehyde	HCHO + aq.
Formalith	Kieselguhr soaked in formaldehyde solution	HCHO
Formin	cf. Hexamin	.....
Formitrol	Formaldehyde	HCHO
Formolyptyol	Formaldehyde	HCHO
Freezing salt	Impure sodium chloride	NaCl
French verdigris	Basic copper acetate	$Cu_2(C_2H_3O_2)_2(OH)_2$
Freund's acid	1-Naphthylamine-3, 6-disulfonic acid	$C_{10}H_9O_6NS_2$
Fuller's earth	Hydrated aluminum and magnesium silicates	.....
Fulminating mercury	Mercuric fulminate	$Hg(ONC)_2$
Fulton white	cf. Lithopone	.....
Fumarole acid	Boric acid	H_3BO_3
Fusel oil	Mixed amyl alcohols	$C_5H_{11}OH$
Galloformin	cf. Hexamin	.....
Gasoline	Benzine or petrol	.....
Gelbin	Barium chromate, or calcium chromate	$BaCrO_4$, or $CaCrO_4 \cdot 2H_2O$
Giallioline	Lead antimoniate	$Pb_3(SbO_4)_2$
Glanzstoff	Cuprammonium artificial silk	.....
Glass liquor	Sodium silicate	$Na_2O \cdot 4SiO_2$
Glass-maker's soap	Manganese dioxide	MnO_2
Glauber's salt	Sodium sulfate	$Na_2SO_4 \cdot 10H_2O$
Glover acid	78% Sulfuric acid	H_2SO_4 + aq.
Gold salts	Sodium aurodichloride	Mixture of $AuCl_3$ and NaCl
Goulard's powder	Lead acetate	$Pb(C_2H_3O_2)_2 \cdot 3H_2O$
GR acid	cf. RG acid	.....
Graham's salt	Sodium metaphosphate	$(NaPO_3)_6$
Grain oil	cf. Fusel oil	.....
Gray antimony	Native antimony trisulfide	Sb_2S_3
Gray powder	Mixture of mercury and chalk	Hg and $CaCO_3$
Green cinnabar	Fired oxides of cobalt and zinc, or a mixture of chrome yellow and Prussian blue	.....
Green copperas	Ferrous sulfate	$FeSO_4 \cdot 7H_2O$
Green nickel oxide	Nickel oxide	NiO
Green verdigris	Basic copper acetate	$2Cu(C_2H_3O_2)_2 \cdot CuO$
Green verditer	Basic copper carbonate, or ground mineral malachite	$CuCO_3 \cdot Cu(OH)_2$
Green vitriol	Ferrous sulfate	$FeSO_4 \cdot 7H_2O$
Griffith's white	cf. Lithopone	.....

TRADE NAMES OF CHEMICALS WITH SYNONYMS AND FORMULAS

Common or Trade Name	Chemical Synonym	Formula
Guignet's green	Chromic oxide and hydroxide (variable)	$Cr_2O_3 \cdot 3H_2O$
Gun cotton	Nitrocellulose	.....
Hahnem auris mercury	Mercurous chloride	HgCl
Halazone	*p*-Dichlorosulfamido-benzoic acid	$Cl_2NSO_2C_6H_4CO_2H$
Halowax	Hexachloronaphthalene	$C_{10}H_2Cl_6$
Hartshorn	Ammonium hydroxide	NH_4OH
Hartshorn salt	Ammonium carbonate-carbamate	$NH_4HCO_3 \cdot NH_2CO_2NH_4$
Heavy carburetted hydrogen	Ethylene	C_2H_4
Hedonal	Methyl-propyl-carbinol urethane	$NH_2CO_2CH(CH_3)C_3H_7$
Helcosol	Basic bismuth pyrogallate	*ca.* $C_6H_5O_4Bi$
Hepar antimony	cf. Crocus of antimony	.....
Hepar calcis	Calcium sulfide	CaS
Hepar sulfuris	Impure potassium sulfide, or calcium sulfide	K_2S, or CaS
Hepatic gas	Hydrogen sulfide	H_2S
Hexamin	Hexamethylene-tetramine	$(CH_2)_6N_4$
Hexil, or hexite	Hexanitro-diphenylamine	$(NO_2)_6C_{12}H_5N$
Hexoram	Hexachloroethane	C_2Cl_6
HNM	Mannitol hexanitrate	$C_6H_8(ONO_2)_6$
Homberg's phosphorus	Fused calcium chloride	$CaCl_2$
Horse brimstone	Impure, dark native sulfur	S
Howard's silver	Mercuric fulminate	$Hg(ONC)_2$
HTH	True calcium hypochlorite	$Ca(ClO)_2$
α-Hydro-juglone	1, 4, 5-Trihydroxy-naphthalene	$C_{10}H_8O_3$
Hydrolith	90% Calcium hydride	CaH_2
Hydrone	Lead-sodium alloy (*ca.* 30% Na)	Pb + Na
Hydrosulfite	Sodium hydrosulfite	$Na_2S_2O_4$
Hypo	Sodium thiosulfate	$Na_2S_2O_3 \cdot 5H_2O$
Imperial green	cf. Paris green	.....
Indanthrene	Dianthraquinone-dihydroazine	$C_{28}H_{14}O_4N_2$
Indanthrone	cf. Indanthrene	.....
Indian red	Ferric oxide	Fe_2O_3
Infusible white precipitate	Dimercuri-diammonium chloride	$N_2H_4Hg_2Cl_2$
Intarvin	Glyceryl margarate	$(C_{16}H_{33}CO_2)_3C_3H_5$
Invert sugar	Mixture of equal parts of glucose and fructose	$C_6H_{12}O_6$
Iron black	Precipitated antimony	Sb
Iron ethiops	Ferroso ferric oxide	Fe_3O_4
Iron mordant	Ferric sulfate	$Fe_2(SO_4)_3$
Iron tartar	Potassium ferrous tartrate	*ca.* $K_2Fe(C_4H_4O_6)_2 \cdot xH_2O$
Iron vitriol	Ferrous sulfate	$FeSO_4 \cdot 7H_2O$
Isonaphthol	β-Naphthol	$C_{10}H_7OH$
James' powder	33.3% Sb_2O_3 and 66.6% $Ca_3(PO_4)_2$	.....
Japanese antimony	Antimony sulfide	Sb_2S_3
Jaune brilliant	Cadmium sulfide	CdS
Javelle water	cf. Eau de Javelle	.....
Jeweller's borax	Sodium tetraborate	$Na_2B_4O_7 \cdot 10H_2O$
Jeweller's rouge	Finest calcined ferric oxide	Fe_2O_3
Julin's carbon chloride	cf. Carbon chloride	.....
K acid	1-Amino-8-naphthol-4, 6-disulfonic acid	$C_{10}H_9O_7NS_2$

TRADE NAMES OF CHEMICALS WITH SYNONYMS AND FORMULAS

Common or Trade Name	Chemical Synonym	Formula
Kainit	Magnesium chloride and potassium magnesium sulfate double salt	$K_2Mg(SO_4)_2 \cdot MgCl_2 \cdot 6H_2O$
Kaiser green	cf. Paris green	.....
Kalle's acid	1-Naphthylamine-2, 7-disulfonic acid	$C_{10}H_9O_6NS_2$
Kalle's salt	Acetone sodium bisulfite	$(CH_3)_2CO \cdot NaHSO_3$
Kasil	Potassium silicate solution	K_2SiO_3 +aq.
King's blue	cf. Cobalt blue	.....
King's gold	Arsenous sulfide	As_2S_3
King's green	cf. Paris green	.....
King's yellow	Arsenous sulfide, or lead chromate	As_2S_3, or $PbCrO_4$
Klee salt	Potassium hydrogen oxalate	$KHC_2O_4 \cdot H_2O$
KMS	Potassium metabisulfite	$K_2S_2O_5$
Knight's patent zinc white	cf. Lithopone	.....
Kontrastin	Pure zirconium oxide	ZrO_2
Koronium bromide	Strontium bromide	$SrBr_2 \cdot 6H_2O$
Lac sulfur(is)	Precipitated sulfur	S
Lamp black	Impure carbon	C
Land plaster	Ground gypsum	$CaSO_4 \cdot 2H_2O$
Landschoff and Meyer's acid	1-Naphthylamine-2, 5-disulfonic acid	$C_{10}H_9O_6NS_2$
Lanolin	Wool grease; cholesteryl esters of fatty acids	.....
Lapis caustic(us)	Potassium hydroxide, or fused silver nitrate	KOH or $AgNO_3$
Laughing gas	Nitrous oxide	N_2O
Laurent's α-acid	1-Nitronaphthalene-5-sulfonic acid	$C_{10}H_7O_5NS$
Lead oxide (brown)	Lead dioxide	PbO_2
Lead plaster	Essentially a mixture of lead oleate with small amounts of glycerol and oleic acid; also lead linoleate	$(C_{17}H_{33}CO_2)_2Pb$, or $(C_{17}H_{31}CO_2)_2Pb$
Lead white	Basic lead carbonate	$2PbCO_3 \cdot Pb(OH)_2$
Lead vinegar	Aqueous solution of basic lead acetate	$Pb(C_2H_3O_2)_2 \cdot PbO$ +aq.
Leipzig yellow	Lead chromate	$PbCrO_4$
Lemon chrome	Barium chromate	$BaCrO_4$
Lencogen	Sodium hydrogen sulfite	$NaHSO_3$
Leucotrope	Benzyl-dimethyl-phenyl-ammonium chloride	$C_{15}H_{18}NCl$
Ley	Sodium hydroxide	NaOH
Leyden blue	cf. Cobalt blue	.....
Lichenic acid	Fumaric acid	$(CH \cdot CO_2H)_2$
Liebman and Studer's acid	1-Naphthol-7-sulfonic acid	$C_{10}H_8O_4S$
Light oil	Coal tar distillate up to 170°C., or any petroleum oil having a high Baume gravity	.....
Ligroin(e)	Petroleum distillate, b. p. 120-35°C.	.....
Lime (unslaked or quick)	Calcium oxide	CaO
Lime (slaked)	Calcium hydroxide	$Ca(OH)_2$
Lime calcium oxide	Calcium oxide	CaO
Lime saltpeter	cf. Saltpeter	.....
Lime water	Aqueous solution of calcium hydroxide	$Ca(OH)_2$ +aq.
Liquid arsenic, fuming	Arsenic trichloride	$AsCl_3$
Liquid glass	cf. Water glass	.....
Lithopone	Zinc sulfide and barium sulfate	$ZnS + BaSO_4$

TRADE NAMES OF CHEMICALS WITH SYNONYMS AND FORMULAS

Common or Trade Name	Chemical Synonym	Formula
Liver of antimony	Impure double sulfide of antimony and alkali or alkaline earth	.....
Liver of sulfur	Mixed potassium sulfides and thiosulfate, or calcium sulfide	.....
Liver ore	Mercuric sulfide (red)	HgS
Lucidol	Benzoyl peroxide	$(C_6H_5CO)_2O_2$
Lunar caustic	Fused silver nitrate	$AgNO_3$
Lunar cornea	Silver chloride	$AgCl$
Lye	Potassium or sodium hydroxide	KOH or $NaOH$
Lysol	Mixture of crude cresols in aqueous soap solution	.....
M acid	1-Amino-5-naphthol-7-sulfonic acid	$C_{10}H_9O_4NS$
Macquer's salt	Potassium arsenate	KH_2AsO_4
Magister of bismuth	Basic bismuth nitrate	$BiO \cdot NO_3 \cdot H_2O$
Magister of sulfur	Amorphous precipitated sulfur	S
"Magistery" of	A precipitate, especially a white precipitate from metallic solutions	.....
Magistery of lead	cf. White lead	.....
Magnesia alba (levis)	Magnesium carbonate	$MgCO_3$
Magnesia usta	Magnesium oxide	MgO
Magnesia white	Magnesium oxide or carbonate	MgO or $MgCO_3$
Malachite (artificial)	cf. Brunswick green	.....
Manganese black	Manganese dioxide	MnO_2
Manganese green	Barium manganate	$BaMnO_4$
Manganese white	Manganese carbonate	$MnCO_3$
Marbon white	cf. Lithopone	.....
Marignac's salt	Potassium stannosulfate	$K_2Sn(SO_4)_2$
Massicot	Unfused lead monoxide	PbO
Meadow green	cf. Paris green	.....
Meat salt	Ammonium fluoride	NH_4F
Melanpyrit	Dulcitol	$C_6H_8(OH)_6$
Mercurius vitae	Mixture of antimony oxychloride and trioxide	$SbOCl + Sb_2O_3$
Mercury chloride, mild	Mercurous chloride	$HgCl$
Mercury red precipitate	Mercuric oxide (red)	HgO
Meta	Metaldehyde	$(CH_3CHO)_3$
Metabisulfite	Sodium metabisulfite	$Na_2S_2O_5$
Methocel	Methyl cellulose	.....
Methyl anol	Methyl cyclohexanone	$CH_3 \cdot C_6H_9O$
Methyl-benzanthrene	9-Methyl-7-*meso*-benzanthrone	$C_{18}H_{12}O$
Methyl-gamma acid	2-Methylamino-8-naphthol-6-sulfonic acid	$C_{11}H_{11}O_4NS$
Methylglycol acetate	Acetate of glycol monomethyl ether	$CH_3CO_2 \cdot C_2H_4 \cdot OCH_3$
Microcosmic salt	Sodium ammonium hydrogen phosphate	$NaNH_4HPO_4 \cdot 4H_2O$
Middle oil	Coal tar distillate, b. p. 170-230°C.	.....
Mild alkali	Sodium carbonate	Na_2CO_3
Mild lime	Calcium carbonate	$CaCO_3$
Milk acid	Lactic acid	$CH_3 \cdot CHOH \cdot CO_2H$
Milk of barium	Suspension of barium hydroxide in water	$Ba(OH)_2$ + aq.
Milk of lime	Suspension of calcium hydroxide in water	$Ca(OH)_2$ + aq.
Milk of magnesia	Suspension of magnesium hydroxide in water	$Mg(OH)_2$ + aq.

TRADE NAMES OF CHEMICALS WITH SYNONYMS AND FORMULAS

Common or Trade Name	Chemical Synonym	Formula
Milk of sulfur	Amorphous sulfur obtained by precipitation	S
Mineral butter	Antimony trichloride	$SbCl_3$
Mineral green	cf. Scheele's green or Brunswick green	.....
Mineral Hamburg	cf. Copper carbonate blue	.....
Mineral orange	Plumbous plumbate	Pb_3O_4
Mineral red	cf. Mineral orange	.....
Mineral white	Barium sulfate	$BaSO_4$
Mitigated caustic	Fused mixture of 1 part silver nitrate and 2 parts potassium nitrate	$AgNO_3 + KNO_3$
Mitis green	cf. Paris green	.....
Mittler's green	cf. Guignet's green	.....
Mixed acid	Mixture of nitric and sulfuric acids	$HNO_3 + H_2SO_4$
Mixed vitriol	Cupric-ferrous sulfate	$CuSO_4 \cdot 3FeSO_4 \cdot 28H_2O$
Mohr's salt	Ferrous ammonium sulfate	$FeSO_4 \cdot (NH_4)_2SO_4 \cdot 6H_2O$
Monomeric liquid	Methyl methacrylate	$CH_2{:}C(CH_3)CO_2CH_3$
Monsel's salt	Basic ferric sulfate	*ca.* $Fe_4(SO_4)_5(OH)_2 \cdot 10H_2O$
Mordant salt	Basic aluminum acetate	$Al(OH)(C_2H_3O_2)_2$
Moss green	cf. Paris green	.....
Mountain green	cf. Brunswick green	.....
Mountain vertditer	cf. Copper carbonate blue	.....
Mu acid or μ-acid	1-Naphthylamine-6-sulfonic acid	$C_{10}H_9O_3NS$
"Muriate of" a metal	Chloride of	.....
Muriatic acid	Hydrochloric acid	HCl
Muriatic ether	Ethyl chloride	C_2H_5Cl
Muthmann's liquid	Acetylene tetrabromide	$(CHBr_2)_2$
Naphtha (petroleum)	Petroleum distillate, b. p. 95-100°C.	.....
Naphtha (solvent)	Coal tar distillate, b. p. 80-110°C.	.....
Naphthalin	Naphthalene	$C_{10}H_8$
α-Naphthol sulfonic acid B	2-Naphthol-8-sulfonic acid	$C_{10}H_8O_4S$
β-Naphthol sulfonic acid S	2-Naphthol-6-sulfonic acid	$C_{10}H_8O_4S$
β-Naphthol disulfonic acid F	2-Naphthol-3, 7-disulfonic acid	$C_{10}H_8O_7S_2$
β-Naphthol disulfonic acid R	2-Naphthol-3, 6-disulfonic acid	$C_{10}H_8O_7S_2$
α-Naphthol disulfonic acid S	cf. Schoellkopf's acid	.....
α-Naphthol disulfonic acid Sch.		
α-Naphthol disulfonic acid		
α-Naphthylamine acids Cl	cf. Cleve's acids	.....
α-Naphthylamine disulfonic acids D	1-Naphthylamine-4, 6- and 4, 7-disulfonic acids	$C_{10}H_9O_6NS_2$
β-Naphthylamine-disulfonic acid R	cf. Amino-R acid	.....
α-Naphthylamine-disulfonic acid S	1-Naphthylamine-4, 8-disulfonic acid	$C_{10}H_9O_6NS_2$
Naples yellow	cf. Antimony yellow	.....
Natron	Sodium carbonate	Na_2CO_3
Natural gas	Mixture of gaseous hydrocarbons	CH_4, etc.
Needle of antimony	Antimony trisulfide	Sb_2S_3

TRADE NAMES OF CHEMICALS WITH SYNONYMS AND FORMULAS

URINE

Normal Range of Composition

Color: slightly yellow to amber
Quantity: 1000 to 1500 cc./24 hrs.
Specific Gravity: 1.008 to $1.030^{15°}$
pH: 5.5 to 7.5
Sugar: 0.015%
Nitrogen { Total: 7 to 20 grams/24 hrs. / Amino Acid: 0.15 to 0.30 grams/24 hrs.
Urea: 12 to 35 grams/24 hrs.
Ammonia: 0.6 to 1.2 grams/24 hrs.
Creatinine: 0.8 to 2.0 grams/24 hrs.
Creatinine Coefficient: 22 to 30 milligrams creatinine per kg. per day.
Uric Acid: 0.3 to 0.8 grams/24 hrs.
Hippuric Acid: 0.7 grams/24 hrs.
Chlorides (NaCl): 10 to 15 grams/24 hrs.
Phosphorus (P): 1.2 grams/24 hrs.
Sulfur (S) { Total: 1.2 grams/24 hrs. / Inorganic: 1.0 grams/24 hrs. / Ethereal: 0.1 grams/24 hrs.
Sodium (Na): 2.5 to 4.0 grams/24 hrs.
Calcium (Ca): 0.1 to 0.3 grams/24 hrs.
Potassium (K): 1.5 to 2.0 grams/24 hrs.
Magnesium (Mg): 0.1 to 0.2 grams/24 hrs.

BLOOD

Volume* and Normal Range of Composition

pH: 7.35 to 7.45
Sugar: 70 to 120 milligrams/100 cc.
Urea: 24 to 32 milligrams/100 cc.
Nitrogen { Non-Protein: 25 to 32 milligrams/100 cc. / Amino Acid: 5 to 8 milligrams/100 cc.
Creatinine: 1 to 2.5 milligrams/100 cc.
Creatine (cells): 6 milligrams/100 cc.
Uric Acid: 2 to 3 milligrams/100 cc.
Chlorides (NaCl): 450 to 500 milligrams/100 cc.
Phosphates (P) (serum): 3 to 7 milligrams/100 cc.
Calcium (Ca) (serum): 9 to 11 milligrams/100 cc.
Cholesterol: 140 to 180 milligrams/100 cc.
CO_2 Combining Power (plasma): 49 to 65 cc./100 cc.

VOLUME { Adult Male: 89.1 cc./kg. body weight, 3410 cc./sq. meter body surface / Adult Female: 84.2 cc./kg. body weight, 3075 cc./sq. meter body surface
PLASMA { Adult Male: 51.0 cc./kg. body weight, 1958 cc./sq. meter body surface / Adult Female: 50.5 cc./kg. body weight, 1848 cc./sq. meter body surface
HEMOGLOBIN { Adult Male: 16.7 grams/100 cc. blood / Adult Female: 14.4 grams/100 cc. blood
RED BLOOD CORPUSCLES { Adult Male: 5 to 6 million/cubic millimeter / Adult Female: 4½ million/cubic millimeter
WHITE BLOOD CORPUSCLES { Adults: 7 to 8 thousand/cubic millimeter / Children: 10 thousand/cubic millimeter

*Rowntree, Brown and Roth, *Volume of Blood and Plasma*, published by W. B. Saunders Co., Philadelphia (1929).

COMPOSITION AND

See also special tables on

Proteins contain the elements of carbon, oxygen, hydrogen, nitrogen and often among others sulfur and phosphorus, thus furnishing the elements for the building and repairing of tissue as well as energy for heat and muscular power. It is supplied by vegetable proteins—grain foods, legumes and nuts, and animal proteins —flesh foods, eggs and dairy foods. *Fats* contain the elements of carbon, hydrogen and oxygen and are utilized for heat and muscular power; the excess is stored as fat in the body. The sources of this type of food are the vegetable and animal fats or oils. *Carbohydrates* contain the elements of carbon, hydrogen and oxygen; they furnish fuel for heat and muscular energy. The excess is transformed and stored in the body as fat. *Water* contains the elements oxygen and hydrogen and is a neutral substance which does not furnish energy but is necessary for the digestive fluids, for transporting soluble substances in the blood and lymph, for maintaining proper dilution of soluble substances in the body, for excreting soluble wastes and for regulating the temperature of the body. It is furnished by fluids taken (water, beverages, soups, etc.), by the water content of solid foods and by that formed in metabolism. *Mineral salts* share in forming bones, teeth, blood, etc. and aid in digestion and metabolism. Among such minerals are the following elements. *Aluminum* occurs only in traces and is probably of very little importance. *Arsenic* is an acid forming element occurring in traces in many animal and vegetable foods; it is probably of very little importance. *Calcium*, a basic forming element, is a sinew and muscle mineral and maintains the bone structure. The amount required per day is 0.7 to 1 gram calcium oxide (CaO). It is supplied by watercress, turnip-tops, dandelions, spinach, lettuce, tomatoes, lemons, oranges, strawberries, cranberries, cheese, milk, buttermilk, wheat, oats, rye, barley, peas, lentils, and nuts. *Chlorine*, an acid forming element, is a secretion mineral. The amount required per day is 6 to 8 grams. It is supplied by table salt, lettuce, spinach, cabbage, beets, parsnips, milk, cheese, strawberries, bananas, pineapples, grapes, potatoes, beans, barley, corn, oats, peas, and sea foods. *Fluorine*, an acid forming element, furnishes a substance needed in building tooth enamel and eye tissue. It is supplied in minute amounts by vegetables, fruits, eggs, milk and seeds. *Iodine*, an acid forming element, is a gland mineral. It is supplied by iodized salt, salt water fish, asparagus, cabbage, green peas, and beans, rice, potatoes, lettuce, mushrooms, tomatoes, grapes, pears, and pineapples. *Iron* is a blood mineral occurring in the red blood cells. USE OF FOODS

Vitamins, and Fats and Oils.

required per day is 0.006 to 0.012 grams. It is supplied by lettuce, spinach, turnip-tops, asparagus, leeks, onions, cabbage, artichokes, radishes, pumpkin, oats, rice, rye, beans, mushrooms, grapes, raisins, strawberries, gooseberries, cherries, prunes, grapefruit, pineapple, currants, and almonds. *Magnesium* is an alkaline forming element which is a cell-building substance maintaining chiefly teeth, bone and muscular tissue. The amount required per day is 0.3 to 0.5 g magnesium oxide (MgO). It is supplied by dandelions, lettuce, watercress, turnip-tops, cabbage, celery, asparagus, tomatoes, berries, lemons, bananas, oranges, limes, pineapple, raisins, almonds, walnuts, wheat, oats, rice, and barley. *Phosphorus* is an acid forming element which is necessary for the building of nervous tissue, bones, and teeth. The amount required per day is 3 to 4 grams of the oxide (P_2O_5). It is supplied by eggs, milk, sea foods, liver, asparagus, cress, turnips, beans, lentils, figs, prunes, currants, apples, berries, wheat, oats, barley, rice, and rye. *Potassium* is a strong alkaline element helping to make the tissues elastic. The amount required per day is 2 to 3 grams of the oxide (K_2O). It is supplied by potato skins, spinach, beans, turnips, parsnips, lettuce, tomatoes, rhubarb, huckelberries, limes, and lemons. *Silicon*, an acid forming element, supplies a substance necessary for building hair, nails, skin and teeth. It is supplied by egg whites, meat, nuts, lettuce, dandelions, asparagus, onions, radishes, cucumbers, celery, strawberries, apples, apricots, cherries, prunes, mushrooms, olives, oats, rye, and millet. *Sodium*, a strongly alkaline element, aids digestion and is a blood and gland mineral. The amount required per day is 4 to 6 grams of the oxide (Na_2O). It is supplied by table salt, spinach, dandelions, cabbage, beets, cauliflower, asparagus, carrots, beets, cucumbers, turnips, strawberries, figs, prunes, apricots, olives, tomatoes and milk. *Sulfur* is an acid element utilized in building protein tissue. The amount required per day is 2 to 3.5 grams of the oxide (SO_3). It is supplied by eggs, cabbage, fish, meats, corn, cheese, brussels sprouts, string beans, lima beans, raspberries, cranberries, and raisins. *Manganese* is a tissue mineral and aids in carrying oxygen from the lungs to the cells. It is supplied in endive, watercress, parsley, almonds, walnuts, and egg yolks.

Abbreviations: A. P., food as purchased including refuse; Ca, calcium; E. P., edible portion of food; Fe, iron; P, phosphorus; var., variable; —, no appreciable amount of vitamin; +, vitamin present; ++, good source of vitamin; +++, excellent source of vitamin; ?, evidence is doubtful.

THE VITAMINS

In compiling data for this revision certain facts became evident in making additions to the previous table. Some of the new factors which have now been added have not as yet been shown to be indispensible to man. The importance of some are only now being recognized and clinical experimentation is practically just beginning. However, it is known that the animal body does not function properly where the intake of these factors is low. Some of these factors have been shown to be synthesized in the intestines of some animals by the intestinal flora and consequently it is very difficult to produce a recognizable deficiency. Almost invariably a deficiency of any factor in man is accompanied by a deficiency of other factors and this gives the chief impetus to preparation of poly-vitamin products. Thus far no factor essential for lower animals, bacteria, etc., has been found which is not also essential for man. Some signs of deficiencies are apparently attributable to more than one vitamin. Some deficiencies are only partially cured by one or another vitamin while complete cure is obtained only by administration of all vitamins concerned. Most of the vitamins are interdependent upon the presence of each other for proper functioning.

INTERNATIONAL VITAMIN STANDARDS

1 Unit vitamin A $\doteq$ 0.6 microgram (μg) or 0.6γ of β-carotene.
1 Unit vitamin B_1 $\doteq$ 3.3 micrograms thiamin chloride.
1 Unit vitamin C $\doteq$ 50 micrograms of *l*-ascorbic acid.
1 Unit vitamin D $\doteq$ 1 milligram of standard solution of irradiated ergosterol (corresponding to 0.1 microgram of the ergosterol used in its preparation or 0.025 microgram crystalline vitamin D_2 (viosterol or calciferol).

Name and Synonym	Physiological Effect	Sources *		
		Concentrates for Medicinal Use	Plant	Animal
Vitamin A Axerophthol Provitamins A (α-, β-, and γ-carotenes, cryptoxanthin, aphanin, aphanicin, echinenone, myxoxanthin, leprotene (and probably other carotinoids) Anti-infective Anti-ophthalmic (Fat soluble)	Increases resistance to infection of eyes, sinuses, ears, kidneys, skin, and mucous membranes. Prevents xerophthalmia, hyperkeratosis of skin and mucous membranes. Promotes appetite and growth. Essential for reproduction. The vitamin is stored in the body and is required at all ages. Deficiency results in night blindness and injury to the nervous system. Adult human requirements approximately 3000 to 5000 units daily.	Carotene, obtained from carrots or vegetables, is converted by the body into vitamin A. Unsaponifiable fractions of halibut liver oil, cod liver oil and other fish liver oils.	All yellow and green vegetables. Raw carrots, yellow turnips, yellow corn, spinach, squash, canned and fresh tomatoes, sweet potatoes, oranges, prunes, apricots and pimento peppers.	Halibut liver oil, cod liver oil and other fish liver oils, fresh milk, cream, butter, cheddar and cream cheese, egg yolk, liver and kidney.
Thiamin chloride Vitamin B_1 Anti-neuritic Anti-beriberi	Promotes appetite and digestion by stimulating metabolism. Vital to health at all ages. Required by the mother for reproduction and lactation. Prevents the diseases beriberi and	Synthetic thiamine chloride. From yeast and wheat germ.	Whole grain cereals, green leafy vegetables, water cress, carrots, canned tomatoes, green	Milk, cheese, raw oysters, brain, kidney and liver.

* See also table: Composition and Use of Foods.

THE VITAMINS (Continued)

(Soluble in water and in 90% alcohol; heat labile; acid stable; adsorbed from acid solution)	polyneuritis. Promotes normal oxidation of carbohydrates in the body and formation of fat from carbohydrates. Adult human requirements approximately 1.5 to 2.0 milligrams daily.		corn, baked potatoes, dried lima beans, turnips and nuts.	
p-Aminobenzoic acid PAB Chromotrichia factor Anti-gray-hair factor	Influences enzyme activity. In experimental rats it apparently prevents achromotrichia. Inhibits oxidation of adrenaline. Nutrilite for certain bacteria. Antagonizes sulfanilamide and sulfapyridine.	Synthetic. Extracts of yeast.	Yeast.	Widely distributed over entire plant and animal kingdoms.
Choline (Choline is replaceable by methionine or betaine with estimated efficacy of 30%)	Maintains integrity of tissues. In chickens it is necessary for normal nutrition and egg production. Deficiency results in marked deposition of liver fat. Acts as transmethylating agent. Deficiency in young rats produces severe renal lesions. Important in lipid metabolism. Deficiency causes a type of cirrhosis of the liver, hemorrhagic degeneration of kidneys, necrosis of kidney cortex, enlargement of spleen. Necessary for normal growth and lactation of rat.	Synthetic choline chloride. As lecithin in phospholipids.	Rice bran, yeast.	Liver. Present in phospholipids of practically all animal and plant cells.
Ascorbic acid Vitamin C Cevitamic acid Anti-scorbutic (Soluble in water; heat labile at alkaline reaction)	Prevents and cures scurvy. Important in formation and maintenance of connective tissue in the body; essential for normal tooth and bone formation and strength of capillary walls. Inhibits dental caries, pyorrhea, certain gum infections, anorexia, anemia, failure of wound healing and susceptibility to infection. Important in carbohydrate metabolism and in controlling infective processes. Body stores readily depleted. Adult human requirements 75 to 100 milligrams daily.	Synthetic *l*-ascorbic acid.	Oranges, lemons, grapefruit, raw and leafy vegetables, raw apples, tomatoes, carrots and paprika.	Adrenal cortex, pituitary, ovary, thymus, intestinal wall, and milk.
Vitamin D Anti-rachitic (Fat soluble)	Prevents and cures rickets in young and osteoporosis in adults. Promotes absorption of calcium and phosphorus, and highly important for normal metabolism of these mineral elements in the young. Prevents spasmophilia and osteomalacia. Limited storage in the body. Approximate human requirements: for premature babies 600 to 800 units with milk; for full term infants 300 to 400 units with milk; for children 300 to 400 units and for pregnant and nursing women 800 units daily.	The effect of this vitamin is produced by the exposure of the body to direct sunlight or ultraviolet light. Ergosterol and foods exposed to (or irradiated with) ultraviolet. Unsaponifiable fractions of liver oils of halibut, cod, and many other fish. Cholesterol and several of its derivatives after exposure to ultraviolet light.	Practically none.	Cod, halibut and other fish liver oils, butter, egg yolk, and fish.

THE VITAMINS

Name and Synonym	Physiological Effect	Sources *		
		Concentrates for Medicinal Use	Plant	Animal
Pantothenic acid Pantothen Filtrate factor Factor II Chick anti-dermatitis factor	Prevents dermatitis in chicks. Deficiency may produce lesions in nervous system or endocrine systems, or may involve skin or hair. May play a part in maintaining integrity of nervous tissue. Necessary in treatment of peripheral neuritis along with other B-vitamins. Prevents hemorrhagic adrenals and achromotrichia in rats. Prevents ulcers in intestinal tract. Essential for growth in various experimental animals and plants. Needed for reproduction in chicks and increases egg hatchability.	Synthetic calcium *d*-pantothenate. Liver and yeast extracts.	Rice bran, wheat bran, brewer's yeast, Irish potato, taro root, alfalfa, wheat germ, molasses, peanuts, cabbage, cucumbers, and rolled oats.	Mammalian liver, egg yolk, eggs, canned salmon, whole milk, kidney, heart, spleen, brain, pancreas, tongue, lung, muscle, beef.
Pyridoxin Vitamin B_6 Adermin Factor Y Anti-dermatitis Anti-acrodynia factor (Soluble in water and in dilute alcohol; heat and acid stable)	Deficiency of this vitamin causes dermatitis in rats; anemia in dogs and pigs, and is presumably essential for hemoglobin formation. In experimental animals deficiency produces convulsions resembling human epileptic fits. Requirements proportional to metabolism. Apparently concerned with metabolism of the aminoacids. Deficiency impairs liver function, produces erythrodemic dermatosis, impairs growth.	Synthetic pyridoxin. From the germ and bran of wheat and rice; yeast, and liver extracts.	Grains, chiefly in the germ, yeast, maize, and molasses, seeds, legumes, spinach, and lettuce.	Liver, heart muscles, milk, and egg yolk.
Riboflavin Vitamin B_2 Vitamin G (Soluble in water and in dilute alcohol; heat and acid stable)	Plays an important role in vision mechanism. In fowls important in production and hatchability of eggs. Deficiency produces cheilosis, glossitis, seborrheic lesions about eyes and nose, vascularizing keratitis, and mild photophobia. Is a component of several enzymes. Plays part in metabolism of amino-acids and carbohydrates. Deficiency produces loss of hair, injury to nervous system, failure to grow, yellow liver, anemia and death. Adult human requirements approximately 2 to 3 milligrams daily.	Synthetic *d*-riboflavin. From milk whey, liver and yeast. Fermentation residues.	Fruits, leafy vegetables, soy beans, wheat germ, yeast.	Kidney, liver, milk, eggs.
Vitamin E α-, β-, and γ-Tocopherols Anti-sterility (Fat soluble)	Absence of this vitamin causes sterility in either sex. It is stored in the body to a certain degree. Exerts favorable influence on growth. Limited value in certain cases of muscular dystrophy and amyotropic lateral sclerosis.	Synthetic *dl*-α-tocopherol. Unsaponifiable fraction of wheat germ oil.	Vegetable oils, lettuce, beans, whole wheat, rice, barley, corn, and water cress.	Meat, liver, milk, and eggs.

* See also table: Composition and Use of Foods.

THE VITAMINS (Continued)

Nicotinic acid Niacin Nicotinic acid amide Niacin amide Anti-pellagra Pellagra preventive (P-P) factor	Prevents and cures black tongue in dogs and pellagra in man. Is a component of several enzymes. Influences carbohydrate, protein, water, and heavy metals metabolism. Deficiency produces a certain type of anemia. Adult human requirement approximately 10 to 20 milligrams daily.	Synthetic nicotinic acid, its amide, and all hydrolyzable nicotinoyl derivatives. From liver and yeast.	Yeast, wheat germ, peas, beans, green leafy vegetables.	Liver, lean meat, milk, egg yolk.
Vitamin K Anti-hemorrhagic Coagulation factor Prothrombin factor Phylloquinones Menadione (2-methyl-1, 4-naphthoquinone) (Fat soluble, heat stable, alkali labile)	Promotes normal blood coagulation time. In chicks it prevents intestinal, subcutaneous and intramuscular hemorrhage. Deficiency reduces prothrombin formation, hemorrhagic diathesis in newborn, certain types of hepatic and biliary diseases.	Synthetic K-vitamers; i.e., many related 1,4-naphthoquinones and compounds readily converted to them, most important is 2-methyl-1, 4-naphthoquinone, which replaces commercially the vitamin, and is known commercially as menadione.	All green vegetables and green leaves, tomatoes, oat sprouts, dried carrot tops, hemp-seed oil, cotton-seed oil, soy-bean oil, and bacterial action on rice bran.	Hog-liver fat, egg yolk, bacterial action on casein and fish meal. K_2 from putrefied fish meal.
Biotin Vitamin H Coenzyme R Anti-egg-white factor Curative factor of egg-white injury Bios II Bios II_b Factor X Factor W	Essential in vital economy of animals and in normal pigment metabolism in animals. Important in intermediary metabolism. Prevents dermatitis. Prevents perosis in chicks and fatty livers. Deficiency results in seborrheic desquamative dermatitis, emaciation and death. Nutrilite for certain bacteria and for yeast. It is antagonized by avidin which occurs in egg white.	Synthetic. Extracts of egg yolk, liver, milk-sugar residues, fermentation residues.	Widely distributed in nature. Yeast, seeds, nuts, tomatoes, carrots, corn and other vegetables.	Liver, kidney, pancreas, egg yolk, pork, and milk. Occurs in small amounts in all mammals and birds, tissue of eye only exception found so far.
Inositol (Meso-inositol) Bios I Anti-alopecia factor	Promotes growth, cures baldness in mice, important in fat metabolism, prevents fatty liver, favors growth of yeast and other microorganisms.	Liver extracts. Wheat bran extracts in the form of the hexa-phosphate ester (phytic acid) which on hydrolysis yields inositol.	Citrus fruits, nuts, yeast, various whole cereals and grains.	Muscle, kidney, liver, brain, milk, and eggs.
Folic acid	Nutrilite for yeast and certain bacteria. Available physiological data thus far is meager. Appears to be a growth factor for rats.	Extracts of yeast, milk sugar residue, spinach.	Yeast, mushrooms. Leaves of many plants.	Milk. Present in all animal tissues.
Citrin Vitamin P Permeability vitamin	Promotes tissue and capillary permeability. Prolongs life of scorbutic guinea pigs. Deficiency causes nutritional purpura.	Extracts of citrus fruits.	Citrus fruit juices and the leaves of several plants.	None.

STANDARDIZATION OF MILK AND CREAM

Pearson's Square Method. Univ. of Illinois Bull. 323

The following procedure is a convenient method for calculating the relative parts by weight of two materials containing the same component but in different amounts which are to be mixed in order to obtain a product in which the component is present in an amount lying between that of the two starting products. Thus, to calculate the relative parts by weight of a 3% butter fat milk and a 40% butter fat cream which would be required in order to obtain 500 pounds of a 5% butter fat milk, proceed as follows: Draw a square and place the number corresponding to the desired % in the center (Fig. 1) and on the two corners at the left place the numbers corresponding to the % of starting materials (Fig. 2); subtract the number in the center of the square from the larger of the two numbers on the left and write this number on the corner diagonally opposite the larger of the numbers on the left (Fig. 3); then subtract the smaller of the two numbers on the left from the number in the center and write the result on the remaining corner (Fig. 4). The two numbers on the right side of the square represent the parts by weight of each of the starting products and which in this example gives the answer that 35/37 of 500 (or 473 pounds) of 3% butter fat milk and 2/37 of 500 (or 27 pounds) of 40% butter fat cream when mixed will give 500 parts of 5% butter fat milk.

*See also a table: *Conversion Table for Quevenne and New York Board of Health Lactometer Readings to Specific Gravity*

TOTAL MILK SOLIDS

The percentage of total milk solids may be calculated from the following expression: (A+B+0.14) = % total solids; where A = % butter fat×1.2; and B = Quevenne lactometer reading × 0.25.

SOLIDS

ing to the % of butterfat, then in the same line with this and in the same column as the observed lactometer reading as given across the top of the table will be found the % of total solids.

Quevenne Lactometer Reading at 15.56°C (60°F)

NATURAL WATERS FOR INDUSTRIAL USE

Cf. W. D. Collins, *Chem. and Eng. News* **21**, *1062 (1943)*.
Reproduced by Permission.

SURFACE AND GROUND WATERS

Typical natural waters available for industrial use in the United States are shown in *Table I*. They have been classified into five types as follows:

Type A. Catskill supply of New York City. This type is a *natural soft water*. For practical purposes it may be considered the equivalent of distilled or rain water and may contain not more than approximately 30 parts per million of dissolved mineral matter. Public water supplies of this type are the Catskill supply of New York City, the supply of Boston and surrounding territory, the Hetch Hetchy supply of San Francisco, and the supply of Asheville, N. C. Rivers and lakes in Maine and other New England states, and streams and lakes in or near mountains may supply these clear waters of low mineral content. The hardness of these natural waters is less than the best that could be obtained by softening methods in use before development of the ion-exchange systems. The very soft waters have a tendency to be corrosive and may require treatment or special precautions to prevent damage from corrosion.

Type B. Niagara River, filtered for public supply of Niagara Falls, N. Y. This type is a *hard water* intermediate between *Type A* and *Type C*. This water, represented by the waters of the Great Lakes, except Lake Superior, is more like the soft waters than the real hard waters. As such it has been used for many domestic supplies but for industrial uses where hardness is detrimental the water must be softened. Public supplies of this type of water are those in Detroit, Milwaukee, Chicago, Cleveland, Sandusky, Toledo, Erie, Buffalo, Niagara Falls, and many smaller places along the lakes and the St. Lawrence River.

Type C. Wells 30 to 60 feet deep used for public supply of Dayton, Ohio. This type is a genuinely *hard water* as commonly used throughout the industrial areas in the heart of the country. These hard waters are the most widely distributed throughout the United States and the water obtained from the wells is so hard that softening is needed to make it acceptable for general domestic use or for most industrial uses.

Type D. Well 2,000 feet deep used for public supply of Maywood, Ill. This type contains enough chloride to require a separate listing. In a few waters nitrate is present as a major constituent but these waters may be classed as variants of the *hard water* type if their total mineral content is in the range of usable waters.

Type E. Well 330 feet deep at Smithfield, Va. This type is representative of a smaller but distinct class of *naturally softened waters*. Their hardness may be well below the average hardness of the waters classed as soft whereas their total mineral content may be well up in the range of the really hard waters. Many of the softened waters in Louisiana and Mississippi are highly colored. The softened, or sodium bicarbonate waters, are found in widely scattered areas but they are somewhat more common in the Atlantic and Gulf Coastal Plain.

NATURAL WATERS FOR INDUSTRIAL USE

Salt Waters. This class may include all waters not considered generally usable. **Sea water** may be taken as the typical salt water. It has about 35,000 parts per million of dissolved salts. Cf. Clarke, "The Data of Geochemistry," *U. S. Geol. Survey Bull.* 770 (*1924*). It is characteristic of sea water that the magnesium greatly exceeds the calcium. Most **brines from inland wells** carry more calcium than magnesium. They also have a smaller proportion of sulfate than sea water and may have much more dissolved mineral matter, often running up to 200,000 or 300,000 parts per million. Such brines may be the raw materials of certain chemical industries.

General Characteristics. An important characteristic of natural waters is the hydrogen-ion concentration. In general the *p H* of natural waters tends to center around 7.0 or a little above. Well waters low in dissolved solid mineral constituents and high in carbon dioxide are often found with a *p H* of 8.0 or more. **Temperature** is an important factor in relation to industrial use. Cf. Collins, "Temperature of Water Available for Industrial Use in the United States," *U. S. Geol. Survey Water-Supply Paper* 520-F (*1925*). Ground waters normally have a constant temperature that is close to the mean annual air temperature for water from depths of 30 to 60 feet. Below 60 feet the temperature increases about 1° F. for each increase in depth of from 60 to 100 feet according to location. Surface water temperatures are variable and not wholly predictable. Reservoirs and lakes may show stratification. In deep lakes a top layer of 20 to 30 feet responds to atmospheric changes while the temperature at greater depths remains constant.

In *Table I* following, the waters used industrially are illustrated by analyses from a report on industrial water supplies that gives analyses for 670 supplies used by about 57,000,000 consumers. The extent to which the five analyses can be taken as representative of waters available for industrial use is as follows:

Type	Number of Supplies	Number of States	Population Supplied
A	131	25	11,170,968
B	75	29	11,581,024
C	47	16	2,153,459
D	19	10	600,785
E	8	3	128,583

Although *Table I* is based on the public supplies of only 670 places, including the larger places in each state, the general conclusions can safely be applied to water supplies that are available for industrial use in the United States. Cf. Collins, Lamar, and Lohr, "The Industrial Utility of Public Water Supplies in the United States, 1932," *U. S. Geol. Survey Water-Supply Paper* 658 (*1934*).

RIVER WATERS

Analyses of river waters are shown in *Table II*. River waters carry widely varying amounts of suspended matter. Some streams regularly have only a few parts per million of suspended matter. At times of heavy rains or rapid melting of snow they

may carry much more. Rivers like the Missouri and Colorado normally carry from a few hundred to several thousand parts per million of suspended matter. The average load in the Missouri is of the order of magnitude of about 2,000 parts per million. The average load of suspended matter in the Colorado River at Grand Canyon, Ariz., is about 1 per cent, 10,000 parts per million. At times the Colorado at Grand Canyon has carried as much as 12 per cent, 120,000 parts per million, for a day. The temperature of river waters follows the changes in air temperature, with a lag that is dependent on many conditions. In a very general way it has been found that the mean monthly temperature of a river water at any point is likely to be within a few degrees of the mean monthly air temperature unless there are conditions that affect the temperature strongly. There is a lag in the rise of spring and early summer temperature in streams that are fed by melting snow.

TABLE I. TYPICAL ANALYSES OF SURFACE AND GROUND WATERS IN THE UNITED STATES

From U. S. Geological Survey Water Supply Paper 658.

Type	(Parts per million) A	B	C	D	E

*Dosage successful in New York City's supply.
†These organisms cause trouble other than odor.
‡These organisms have been affected by chlorine producing characteristic odor and in many cases controlled by dosage ranging from 0.3 to 3.0 ppm, depending largely upon the amount of organisms.
§Controlled by excess caustic lime, 5 ppm in the case of diatoms (48 hrs.).

DRINKING WATER STANDARDS

Condensed from Standards adopted by the United States Treasury Department, September 25, 1942.

As to Bacteriological Quality.

Applications *A1* and *A2* shall govern when ten-milliliter (10 ml) portions are used and applications *B1* and *B2* shall govern when one hundred-milliliter (100 ml) portions are used.

(*A1*) Of all the standard ten-milliliter (10 ml) portions examined per month in accordance with specified procedure, not more than ten (10) per cent shall show the presence of organisms of the coliform group.

(*A2*) Occasionally three (3) or more of the five (5) equal ten-milliliter (10 ml) portions constituting a single standard sample may show the presence of organisms of the coliform group, provided that this shall not be allowable if it occurs in consecutive samples or in more than:

(*a*) Five (5) per cent of the standard samples when twenty (20) or more samples have been examined per month.

(*b*) One (1) standard sample when less than twenty (20) samples have been examined per month.

(*B1*) Off all the standard one hundred-milliliter (100 ml) portions examined per month in accordance with the specified procedure, not more than sixty (60) per cent shall show the presence of organisms of the coliform group.

(*B2*) Occasionally all of the five (5) equal one hundred-milliliter portions constituting a single standard sample may show the presence of organisms of the coliform group, provided that this shall not be allowable if it occurs in consecutive samples or in more than:

(*a*) Twenty (20) per cent of the standard samples when five (5) or more samples have been examined per month.

(*b*) One (1) standard sample when less than five (5) samples have been examined per month.

As to Chemical and Physical Characteristics.

The water shall be clear and colorless with no objectionable taste or odor and shall not contain an excessive amount of soluble mineral substance, nor excessive amounts of any chemical employed in treatment.

For waters softened by the lime soda process the total alkalinity produced should not exceed the hardness by more than 35 ppm (calculated as $CaCO_3$).

For chemically treated waters the phenolphthalein alkalinity (calculated as $CaCO_3$) should not be greater than 15 ppm plus 0.4 times the total alkalinity. This requirement limits the permissible *pH* to about 10.6 at 25°C. The normal carbonate alkalinity should not exceed 120 ppm.

DRINKING WATER STANDARDS

Lead (Pb) shall not exceed 0.1 ppm. Arsenic shall not exceed 0.05 ppm.
Fluorides shall not exceed 1.0 ppm. Selenium shall not exceed 0.05 ppm.

Salts of barium, hexavalent chromium, heavy metal glucosides or other substances with deleterious physiological effects shall not be permitted in the water supply system.

The following chemical substances which may be present in natural or treated waters should preferably not occur in excess of the following concentrations where other suitable supplies are available:

Copper (Cu) should not exceed 3.0 ppm. Zinc (Zn) should not exceed 15 ppm.
Iron (Fe) and manganese (Mn) together should not exceed 0.3 ppm.
Magnesium (Mg) should not exceed 125 ppm.
Chloride (Cl) should not exceed 250 ppm.
Sulfate (SO_4) should not exceed 250 ppm.
Phenolic compounds should not exceed 0.001 ppm in terms of phenol.

Total solids should not exceed 500 ppm for a water of good chemical quality. However, if such water is not available, a total solids content of 1,000 ppm may be permitted.

STABLER'S REACTION COEFFICIENTS

The valence of a radical divided by its atomic or molecular weight.

Positive ions	Reaction Coefficient	Negative ions	Reaction Coefficient
Aluminum, Al	0.1112	Bicarbonate, HCO_3	0.0164
Calcium, Ca	0.0499	Carbonate, CO_3	0.0333
Hydrogen, H	0.9922	Chloride, Cl	0.0282
Iron, Fe"	0.0358	Hydroxide, OH	0.0588
Magnesium, Mg	0.0822	Nitrate, NO_3	0.0161
Potassium, K	0.0256	Sulfate, SO_4	0.0208
Sodium, Na	0.0435		
	Alkalinity, $CaCO_3$	0.0200	
	Free CO_2, CO_2	0.0454	

The reacting value of a radical, which is identical with the terms "milliequivalent" or "milligram equivalent" of other writers, is obtained by use of the above table; the parts per million of a radical multiplied by its reaction coefficient gives the reacting value of that radical; for example, if a water analysis showed the sample to contain 25 parts per million of magnesium then the reacting value of Mg, written rMg, would be 25×0.0822 or 2.055.

FORMULAS FOR WATER SOFTENING REQUIREMENTS

The terms in the formulas are in parts per million except those expressed as reacting values (r). Abbreviations: Alk—alkalinity as $CaCO_3$; TH—total hardness as $CaCO_3$.

Pounds of lime (90% CaO) required per 1000 gal.

$$0.26\ (r\mathrm{Fe}+r\mathrm{Al}+r\mathrm{Mg}+r\mathrm{H}+r\mathrm{HCO_3}+r\mathrm{CO_2})$$

or $$0.00931\mathrm{Fe}+0.0288\mathrm{Al}+0.0214\mathrm{Mg}+0.258\mathrm{H}+0.00426\mathrm{HCO_3}+0.0118\mathrm{CO_2}$$

Other simpler formulas for this computation are:

$$0.26\ (r\mathrm{CO_2}+r\mathrm{Mg}+r\mathrm{Alk})$$

or $$0.26\ [r\mathrm{Na}+r\mathrm{Ca}+2r\mathrm{Mg}+r\mathrm{CO_2}-(r\mathrm{SO_4}+r\mathrm{Cl})]$$

or $$0.0052\ (4.115\mathrm{Mg}+\mathrm{Alk}+2.27\ \mathrm{CO_2})$$

or $$(0.44\ \mathrm{Alk}+\mathrm{CO_2})\times 0.0118+[4.115\ \mathrm{Mg}\times 0.0052]$$

Pounds of soda ash (58% test or 100% pure) required per 1000 gal.

$$0.44\ (r\mathrm{Fe}+r\mathrm{Al}+r\mathrm{Ca}+r\mathrm{Mg}+r\mathrm{H}-r\mathrm{CO_3}-r\mathrm{HCO_3})$$

or $$0.0157\mathrm{Fe}+0.0489\mathrm{Al}+0.022\mathrm{Ca}+0.0362\mathrm{Mg}+0.437\mathrm{H}-0.0147\mathrm{CO_3}-0.0722\mathrm{HCO_3}$$

Other simpler formulas for this computation are:

$$0.44\ (r\mathrm{Ca}+r\mathrm{Mg}-r\mathrm{Alk})$$

or $$0.44\ [(r\mathrm{Ca}+r\mathrm{Mg})-r\mathrm{CO_3}]$$

or $$0.0088\ (4.115\ \mathrm{Mg}+2.495\ \mathrm{Ca}-\mathrm{Alk})$$

or $$0.0088\ (\mathrm{TH}-\mathrm{Alk})$$

HEAT OF COMBUSTION OF COAL FROM ANALYSES

The usual formula employed in calculating the heat of combustion of coal from an ultimate analysis is that of Dulong:

$$\text{BTU/pound} = 14{,}544C + 62{,}028\left(H - \frac{O}{8}\right) + 4050S$$

where C, H, O, and S are the decimal percents of carbon, hydrogen, oxygen, sulfur found on ultimate analysis made on the "as received" basis.

A proximate analysis of coal gives moisture, volatile matter, fixed carbon and ash. It is possible to compute the heat of combustion of coal from the values obtained in a proximate analysis by first finding the percent of carbon, hydrogen and oxygen by means of the formulas below and then substituting in Dulong's formula given above.

The method is as follows:—From the values of a proximate analysis find the percent of volatile matter (V) and fixed carbon *on an ash- and moisture-free basis.* These two values should add up total 100%. Then,

$$\%H = \%V\left(\frac{7.35}{\%V+10} - 0.013\right)$$

%N = 0.07V for anthracite and semi-anthracite coals.
%N = 2.10 − 0.012V for bituminous and lignite coals.
%C = Fixed C + $0.02V^2$ for anthracite coals.
%C = Fixed C + 0.9 (V − 10) for semi-anthracite coals.
%C = Fixed C + 0.9 (V − 14) for bituminous coals.
%C = Fixed C + 0.9 (V − 18) for lignite.

Sulfur increases V, therefore the volatile carbon is too high by the extent of the sulfur in the coal.

Example.—A bituminous coal from Jefferson, Pa. gives a proximate anaylsis as follows: moisture, 2.59%; volatile matter, 30.41%; fixed carbon, 59.08%; ash, 7.9%. The %ash plus %moisture = 7.9 + 2.59 = 10.49
Therefore,

$$\frac{30.41}{100-10.49} \times 100 = 33.97\% \text{ volatile matter on ash- and moisture-free basis.}$$

$$\frac{59.08}{100-10.49} \times 100 = 66.00\% \text{ fixed carbon on ash- and moisture-free basis.}$$

$$H = 33.97\left(\frac{7.35}{33.97+10} - 0.013\right) = 5.23\%H$$

N = 2.10 − 0.012 × 33.97 = 1.69%N
C = 66.00 + 0.9 (33.97 − 14) = 83.97%C
83.97 × 0.8951 = 75.16%C as received
5.23 × 0.8951 = 4.68%H as received
1.69 × 0.8951 = 1.51%N as received
7.9% ash
2.59% moisture
91.84%, therefore 100 − 91.94 = 8.16% oxygen

Then by substitution of the values above in the Dulong formula

$$14{,}544 \times 0.7516 + 62{,}028\left(0.0468 - \frac{0.0816}{8}\right) = 13{,}201 \text{ BTU/pound.}$$

The experimental value reported for this coal was 13,860 BTU/pound.

FLAME TEMPERATURES

Reprinted by permission from "Combustion Flames and Explosions of Gases," by Lewis and von Elbe, published 1938 by Macmillan.

Except as noted otherwise, the flame temperatures listed in the following table were determined by the sodium line-reversal method with a totally colored flame for moist mixtures at room temperature. The values given are the maximum flame temperatures determined for the given combustible or combination of combustibles with inert gas. In a few cases a number of values are given for different mixture compositions. All compositions are given on the dry basis.

The experimental flame temperatures are probably all influenced somewhat by heat losses, excitation lag and intermixing with the surrounding atmosphere. However, these disturbances do not cause excessive discrepancies from the theoretical flame temperatures, and the values may be taken as an approximate indication of the flame temperatures of the mixtures given.

A large number of calculated flame temperatures are to be found in the literature. They are not included in the table because they are generally based on inexact thermochemical data. Similarly, many experimental values have been omitted, since they were determined under specialized and sometimes ill-defined conditions.

COMBUSTION CON-

The high (gross) heat value is the value obtained by burning the gas in a Junker's calorimeter, which assumes that the products of combustion are cooled to the initial temperature and includes the heat of condensation of the water formed by the combustion; the low (net) heat value differs from the high (gross) value by the heat of vaporization of water and is calculated from the gross by subtracting the heat of

COMPOSITION AND PHYSICAL PROPERTIES OF ALLOYS

See also the table *Corrosion- and Heat-Resistant Alloys.*

The following table has the alloys arranged alphabetically according to the name of the element which predominates. The following abbreviations are employed: A, annealed; C, cold worked; AC, annealed and cold worked; H, hardened; HR, hot rolled. The ultimate strength is given in thousands of pounds per square inch.

Composition %	Trade Name	Sp. Gr.	M. P. °C.	Thermal Expansion $\times 10^6$	Ultimate Strength
Aluminum					
99.2Al	Aluminum 2S	2.71	660	23.94	12AC
95Al, 5Cu	Lynite, body alloy	.....	650	26	.....
94Al, 4Cu, 0.5Mg, 0.5Mn, coated with 99.7+Al	Alclad 17 ST	2.96	538-46	21.96	55

*This alloy (Lipowitz's alloy) and many others can be alloyed with mercury to further reduce the melting point; after melting the alloy and removing the molten mass from the source of heat, the mercury is introduced and the mixture stirred with an iron rod. **CAUTION:** mercury vapors are poisonous.

CORROSION AND HEAT-RESISTANT ALLOYS

Composition, Trade Name and Manufacturer

By *Clayton E. Plummer (1) and Richard K. Akin (2)*

(1) Director of Chemical and Metallurgical Engineering Departments, (2) Research Metallurgist; with the Robert W. Hunt Co., Engineers and Consultants on Engineering Materials. 175 West Jackson Boulevard, Chicago, Ill.

Key to Classification

1: Aluminum (Al)	**AA: 5 to 6%**	**aa: 0.07% Maximum Carbon**
2: Chromium (Cr)	**A: 7 to 11%**	**a: 0.12% Maximum Carbon**
3: Cobalt (Co)	**B: 12 to 15%**	**b: 0.13-0.20% Carbon**
4: Copper (Cu)	**C: 16 to 23%**	**c: 0.21-0.35% Carbon**
5: Manganese (Mn)	**D: 24 to 30%**	**d: 0.36-0.50% Carbon**
6: Molybdenum (Mo)	**E: 31 to 39%**	**e: 0.51-0.65% Carbon**
7: Nickel (Ni)	**F: 40 to 48%**	**f: 0.66-0.80% Carbon**
8: Silicon (Si)	**G: 49 to 57%**	**g: 0.81-1.10% Carbon**
9: Tungsten (W)	**H: 58 to 66%**	**h: above 1.10% Carbon**
10: Tantalum (Ta)	**J: 67 to 75%**	
Sulfur (S)	**K: 76 to 84%**	
Vanadium (V)	**L: 85 to 100%**	

The chemical analysis of the Allegheny Metal, the low carbon iron-chromium-nickel alloy, for example, is: chromium 18%; nickel 8%; 0.12% maximum carbon.

This is 2(Cr) C(16-23%) for the chromium content; 7(Ni) A(7-11%) for the nickel content; and a (0.12% maximum for the carbon content.

Thus an alloy of this chemical composition would be classed as 2C 7A a. The predominating alloying element is placed first; the lesser alloying elements follow in order of their decreasing proportions.

By reason of their chemical analyses, these alloys divide themselves into natural groups.

These are: The 2B group (chromium alloys) stainless steels resistant to atmospheric and weak acid corrosion; the 2C group, more resistant to atmospheric corrosion and nitric acid; the 2D group, resistant to atmospheric and nitric acid corrosion and resistant to wear; the 2CD 7ABCD group (chromium-nickel alloys), resistant to atmospheric corrosion, oxidation at high temperatures and to nitric acid; the 7CDEFGHJ 2ABCD groups, resistant to atmospheric corrosion, oxidation at high temperatures and nitric acid; the 7H 2C 4A, the 7H 6C, the 8B, and the 10L groups resistant to certain acids.

10 L
270 Tantalum (99.5%)

The elements iron, chromium, nickel, cobalt, molybdenum, tungsten, silicon, and tantalum, have yielded numerous alloys possessing useful properties where resistance to corrosion is required. For the most part chromium and nickel predominate as the alloying elements with iron. The chromium iron alloys admirably resist most conditions of corrosion and oxidation. Increasing the chromium content gives increased resistance to oxidation both at room and elevated temperatures, provided the carbon content is constant. If the carbon content is increased within certain ranges a corresponding increase in chromium also is necessary to obtain the best corrosion resistance. The ratio of chromium to carbon should be 15% plus 16 times the carbon content, if the alloy is to be resistant in the annealed condition.

Although the chrome alloys may be welded electrically or by the oxy-acetylene torch, the welds are more or less brittle due to grain growth resulting from welding heat. In order to prevent oxidation, the flame should be neutral or slightly reducing.

Coated rods are generally recommended for electric welding and uncoated rods for gas welding.

Where both resistance to corrosion and erosion are desired, the high chromium alloys are very valuable, but in no case will any chromium alloy withstand the action of hydrochloric acid.

The commercially important stainless alloys may be divided into eight principal groups as follows:—

CHROMIUM IRON ALLOYS

GROUP I 2AA CHROMIUM 5—7%

This group of alloys is easily forged and made into sheets, wire, seamless tubes, etc. It finds application in the oil industry, where more corrosion resistance is desired than can be obtained by the use of the straight carbon steels. An addition of five to seven percent chromium gives this steel a life of approximately three times that of the carbon steels and, therefore, finds application where corrosive conditions warrant additional cost per pound.

GROUP II 2B CHROMIUM 12—16%

This group may be divided into three sub-groups, depending upon the carbon content:—

1. **Rustless or Stainless Iron—Carbon 0.10% maximum.**

This class is fabricated in the form of castings, forgings, hot rolled bars, cold rolled or drawn bars, plates and sheets, strips, tubes, and wire, and is used where corrosive conditions are not severe. The low carbon 14% chromium alloys will resist concentrated nitric acid, but higher percentages of chromium are necessary for resistance to dilute nitric acid.

2. **Cutlery Stainless—Carbon 0.3%**

Increasing the carbon content from 0.1 to 0.3% gives an alloy that was originally used for cutlery. The higher carbon reduces the corrosion resistant properties.

3. **Dies — Carbon 1—2%.**

Increasing the carbon to 2% produces a steel with abrasion resistance, but at the same time the higher carbon content lowers the corrosion resistance.

GROUP III 2C CHROMIUM 16—20%

1. **High Chromium Stainless-Iron—Workable Alloys—Carbon 0.12%**

This group is fabricated in the form of castings, forgings, hot rolled bars, sheets, strips, tubes, and plates. It shows heat resistance up to 1600°F. and requires no heat treatment to bring out its stainless properties. It is suitable for forming and drawing, provided the operation is not too drastic, and finds its principal application in the synthetic ammonia process. The alloy shows excellent resistance both to concentrated and dilute nitric acid.

2. **High Carbon Stainless Steel—Carbon 0.6%.**

A typical composition of these alloys is chromium 16.5%, and carbon 0.65%. This type of alloy possesses a more intense hardness and not only has a better cutting edge than the lower chromium alloy, but also a more pleasing appearance.

GROUP IV 2D CHROMIUM 25—30%

1. **Carbon Less Than 0.3%—Workable Alloys.**

The workable alloys do not usually contain more than 0.3% carbon. The increased chromium content produces an alloy which is extremely resistant to nitric acid and oxidation at elevated temperatures. These alloys are not very ductile when cold and should be heated to a cherry red before deformation.

2. **Stainless Castings — Medium Carbon.**

The 24 to 30% chromium alloys are very resistant to sulfur and sulfur gases and are generally recommended for use in oxidizing atmospheres up to 2100°F. An enamel-like coating of oxide forms at approximately 1700°F., to protect the metal from further attack. These castings are used in the form of pumps for handling mine water; they also show excellent resistance to nitric acid.

3. **Abrasion Resistant Alloys—Carbon 1—3% High Carbon.**

Where greater resistance to erosion is desired, higher carbon contents are used.

CHROMIUM-NICKEL ALLOYS

GROUP V 2C 7A 18% CHROMIUM—8% NICKEL

There are various modifications within this group. Small percentages of silicon, molybdenum, tungsten, copper, and aluminum are often added to give either strength at elevated temperatures or increased corrosion resistance against certain chemicals. These alloys are fabricated in the form of castings, forgings, hot rolled bars, cold rolled or drawn bars, plates and sheets, strips, tubes, and wires. Appearance and ease of fabrication are dominating considerations; this alloy combines beauty of appearance and permanence in service. This alloy shows carbide precipitation when held at 800 to 1450°F. One of the large manufacturers of stainless alloys uses titanium to stabilize the alloy in order to reduce the probability of inter-granular corrosion.

It finds wide application in the chemical industry as material for autoclaves, condensers, stills, digesters, pipe lines, fittings, bolts and nuts, heat exchangers and evaporators; it is used in nitric acid plant equipment as pipe lines, vats, cocks, valves, towers, tank cars, and drums; it is also employed in furnace parts such as skid bars, conveyors, sills, and doors; refrigerating machinery and equipment, and soap manufacturing equipment often employ this alloy.

Although this alloy is considered "stainless," it is not recommended for use with chlorine, bromine, iodine, or halogen acids. It is recommended, however, as being fully resistant to the following at their respective boiling points:—10% acetic acid, acetic anhydride, acetone, 20% sodium hydroxide, 10% aluminum sulfate, ammonia water, 10% ammonium chloride, ammonium nitrate, boric acid, carbolic acid, carbonate of soda, 15% citric acid, copper sulfate, dilute and concentrated nitric acid, potassium chlorate, sodium sulfide, sweet water, and zinc sulfate.

GROUP VI 2D 7B 25% CHROMIUM—12% NICKEL

Metallurgically, this group is similar to the 18 chromium, 8 nickel alloy, and their fabricating characteristics are quite similar. This alloy, however, is tougher than the 18-8. The main application for this group is for heat resistance between 1500 and 2100°F. The higher percentages of chromium and nickel produce an alloy with exceptional oxidation resistant properties; because this alloy is more expensive than the others of the stainless series, it finds only a limited application.

HEAT RESISTANT ALLOYS
NICKEL-CHROMIUM

GROUP VII 7E 2C Approx. 38% NICKEL—18% CHROMIUM

This group containing approximately 38% nickel, 18% chromium, and 0.5% carbon is fabricated in the form of castings, plates, shapes and wire, and is intended for high temperature service as furnace parts, chains, rails, retorts, carburizing boxes, annealing containers, and general parts for service at elevated temperatures.

GROUP VIII 7H 2C Approx. 67% NICKEL—20% CHROMIUM—1.5% SILICON—1% MANGANESE—1.5% CARBON

When resistance to higher temperatures is desired, an alloy containing more nickel is recommended. Alloys such as are represented in this group are widely used for carburizing containers and parts at operating temperatures up to 2200° F. These high nickel-chromium alloys have proven their merit under widely varying conditions of many plants. Some classes of these alloys with low carbon content are drawn into wire and used for electrical purposes. The introduction of these low carbon alloy wires made possible the development of present day electrical heating equipment. A large amount of the wire used has an analysis of approximately 60% nickel, 15% chromium, 0.12% carbon, and the balance iron. When greater resistance to corrosion is demanded and the additional expense warrants its use, an alloy containing 80% nickel and 20% chromium is used. In the best grades of electrical heating elements there is only a small percentage of iron present.

In conclusion, materials which are highly resistant to one agent such as nitric acid, may prove entirely incapable of resisting another one such as hydrochloric acid. Chromium imparts resistance to nitric acid. Molybdenum imparts resistance to hydrochloric or sulfuric acid. High silicon alloys (14% silicon), are fairly resistant to sulfuric, nitric, or hydrochloric acid. The metal tantalum is very resistant to hydrochloric, nitric, or sulfuric acid.

Nickel-molybdenum-iron alloys containing approximately 60% nickel and 20% molybdenum are very resistant to hydrochloric and sulfuric acids. An alloy has been developed which is very resistant to nitric, hydrochloric, or sulfuric acid, and to wet chlorine. This alloy contains nickel, chromium, molybdenum, tungsten, and iron; the chromium imparts resistance to nitric acid, the nickel and molybdenum impart resistance to hydrochloric and sulfuric acids.

When considering the use of corrosion resistant alloys in any new commercial application, the prospective user should not place too much faith in the published data. Wherever possible, test pieces should be subjected to the corrosive conditions of actual operation and these "indicators" studied critically. The selection of the proper metal for a specific application should be made under the direction of metallurgists or engineers, who are familiar with the latest developments in these alloys.

ETCHING SOLUTIONS FOR FERROUS ALLOYS

Used to Show	Composition of etching solution	Remarks
For Macroscopic Examination		
Segregations	1 part conc. hydrochloric acid, HCl 1 part water	Use at 100 to 212° F. Etch for ½ hour or until defects are brought out.
Segregations	5 g picric acid, $HOC_6H_2(NO_2)_3$ 100 cc ethyl alcohol, C_2H_5OH	Etch for 4 to 5 hours.
Phosphorus segregations	10 g cuprous ammonium chloride, $CuCl{\cdot}NH_4Cl{\cdot}6H_2O$ 100 cc water	This solution is more easily prepared than are most copper chloride solutions.
Phosphorus segregations	10 g cupric chloride, $CuCl_2$ 40 g magnesium chloride, $MgCl_2$ 20 cc hydrochloric acid, HCl 180 cc water 1000 cc absolute alcohol, C_2H_5OH	Absolute methyl alcohol, CH_3OH, may be used in place of ethyl alcohol.
Variations in crystal structure, and segregations	20 g ammonium persulfate, $(NH_4)_2S_2O_8$ 100 cc distilled water	Use at room temperature. A very good reagent for the purpose indicated.
To reveal the structure of welds and to distinguish between steel and wrought iron	1 part conc. nitric acid, HNO_3 3 parts of water	Use at about 100° F.
For Microscopic Examination		
The general structure of normal iron and steel	4 g picric acid and 95 cc of absolute alcohol, or 5 g picric acid and 100 cc of 95% alcohol, C_2H_5OH	Keep bottle well stoppered when absolute alcohol is used.
The general structure of normal iron and steel	5 cc nitric acid, HNO_3 100 cc of ethyl alcohol, C_2H_5OH	For heat treated steels use a more dilute solution.
To establish the difference between hardened and normal steels	4 parts nitric acid, HNO_3 96 parts iso-amyl alcohol, $C_5H_{11}OH$	
Sorbitic and troostitic constituents	1 part of a 40% solution of nitric acid in acetic anhydride 1 part methyl alcohol, CH_3OH 1 part ethyl alcohol, C_2H_5OH 1 part iso-amyl alcohol, $C_5H_{11}OH$	Colors troostite and troosto-sorbite.

ETCHING SOLUTIONS FOR FERROUS ALLOYS

Used to show	Composition of etching solution	Remarks
Cementite and other carbides, and tungstites	2 g picric acid, $HOC_6H_2(NO_2)_3$ 24.5 g sodium hydroxide, NaOH 73.5 cc water	Use boiling for 5 or 10 minutes. Tungsten carbide is unaffected, but other carbides and tungstides are colored.
Structure of stainless steels	10 g ferric chloride, $FeCl_3$ 30 cc hydrochloric acid water to make total volume 120 cc	May be diluted, and applied gently with a piece of cotton. Time required is less than 30 seconds.
Structure of stainless steels	30 cc hydrochloric acid, HCl 10 cc nitric acid, HNO_3 80 cc glycerol (glycerine)	Use full strength for rapid work, but handle carefully.
Carbides and tungstides in high-speed and tungsten steels	10 g potassium ferricyanide, $K_3Fe(CN)_6$ 10 g potassium hydroxide, KOH 100 cc water	Use hot.
Structure of high-speed steel and tungsten carbide	10 cc commercial hydrogen peroxide, H_2O_2 20 cc of a 10% aqueous sodium hydroxide (NaOH) solution	Use fresh from 10 to 12 minutes. Tungsten carbide is darkened.
Structure of stellite, high-chrome steels, etc.	Use a low electric current through a solution of 0.5 g sodium hydroxide (NaOH) in 100 cc of water.	Use two 4 c.p. lamps in series on a 110-volt D. C. circuit. Cover the specimen with the solution; make contact with one wire at the side and dip the other with the solution moving so as to obtain a uniform etch.

ETCHING SOLUTIONS FOR NON-FERROUS ALLOYS

Metal or Alloy	Composition of etching solution	Remarks
Copper Base Alloys		
Copper or Cu-Al alloys	5 g copper-ammonium chloride 120 cc water Add conc. ammonium hydroxide until the precipitate which forms is redissolved, giving a clear blue color.	Etch from 30 to 60 seconds; this is a very good copper etch.
Copper, brasses, Cu-Al alloys, German silver	A 10% solution of ammonium persulfate, $(NH_4)_2S_2O_8$	Etch from 1 to 2 minutes. Keep the surface of the specimen free from grease.
Copper or brasses	10 cc hydrogen peroxide, H_2O_2 40 cc conc. ammonium hydroxide, NH_4OH	Apply with a swab to the surface of polished specimen. Rub briskly until mirror-like surface is obtained.

ETCHING SOLUTIONS FOR NON-FERROUS ALLOYS

Metal or Alloy	Composition of etching solution	Remarks
Copper Base Alloys		
Brasses (Used for copper products such as sheets, rods, etc.), Cu-Al alloys, German silver	15 cc of a saturated ferric chloride ($FeCl_3$) solution 30 cc concentrated hydrochloric acid, HCl 200 cc water	Use this solution after the ammoniacal peroxide solution above. Dip the specimen into this ferric chloride solution for a few seconds after following the directions above.
Cu-Al alloys	Nitric acid (HNO_3), sp. gr. 1.42	Time for etching is very short. It is difficult to control the intensity of the attack.
Aluminum and Light Alloys		
Al and Al alloys	0.5 to 20% hydrofluoric acid (HF) acid solutions. The aqueous or alcoholic solutions are used.	Etch for about 15 seconds. Remove the black deposit so formed by immersing for a short time in conc. nitric (HNO_3) acid. $CuAl_2$ and $FeAl_3$ are darkened by HF.
Aluminum	45 cc conc. hydrochloric acid, HCl 15 cc conc. nitric acid, HNO_3 15 cc hydrofluoric acid, HF 25 cc hot water	This etch generally requires only a few seconds.
Al alloys	10 cc conc. nitric acid, HNO_3 3 to 4 cc hydrofluoric acid, HF 86 to 87 cc hot water	
Al and Al alloys	10 to 20% aqueous sulfuric acid (H_2SO_4) solution	Heat to 160°F., immerse specimen for a few seconds, quench in cold water. $FeAl_3$ is stained black.
Al and Al alloys	10 cc conc. hydrofluoric acid, HF 15 cc conc. hydrochloric acid, HCl 90 cc water	Etch from 30 to 90 seconds. Reveals grain size very clearly.
Lead, Tin, Zinc and Their Alloys		
Used for zinc	6% chromic acid, 94% nitric acid	Add a few drops of this solution to 100 cc of water before using.
Tin alloys	2% alcoholic nitric acid solution	
Lead alloys	5% aqueous nitric acid solution	

ETCHING SOLUTIONS FOR NON-FERROUS ALLOYS

Metal or Alloy	Composition of etching solution	Remarks
Lead, Tin, Zinc and Their Alloys		
All "white metals"	Hydrochloric acid, either dilute or concentrated, depending upon the composition of the alloy. A 5% solution is best for an alloy rich in zinc.	When a concentrated solution is used, dip the specimen in the acid for a few seconds, wash carefully, and dry.
Alloys rich in zinc or cadmium	1 part iodine 3 parts potassium iodide, KI 10 parts water	
Alloys of lead, tin, antimony, bismuth, and anti-friction metals	5% aqueous solution of silver nitrate, $AgNO_3$	
Antimony and lead alloys, and babbit metal	10 g ferric chloride, $FeCl_3$ 30 cc hydrochloric acid, HCl, sp. gr. 1.19 120 cc water	A good etching solution for the metals named.
Miscellaneous Metals and Alloys		
Nickel and its alloys	50 cc of 70% nitric acid, HNO_3 50 cc of 50% acetic acid, $HC_2H_3O_2$	This is *Merica's solution*. It is very good for cast, cold drawn, and annealed nickel.
Nickel and its alloys	20 to 40 cc of nitric acid, HNO_3 30 to 40 cc of 75% acetic acid, $HC_2H_3O_2$ 30 to 40 cc acetone, $(CH_3)_2CO$	This solution is very similar in action to the one above.
Magnesium and its alloys	2% aqueous nitric acid solution	Etch for about 10 seconds.
Gold, silver, platinum, and other noble metals*	1 part nitric acid, HNO_3 5 parts hydrochloric acid, HCl 6 parts water	Use at about 60°F.
Dow metals (90-96% Mg, 4-12% Al, 0.1-0.3% Mn)	2% aqueous oxalic acid solution, $H_2C_2O_4$	Swab during etching. Rinse with water, then with alcohol, and dry with a blast of warm air.

* For Au-Cu and Au-Ag alloys it is better to saturate the etching solution with either sodium chloride or ammonium chloride.

GLASS LINED AND ENAMELED STEEL

(A) Coefficients of Heat Transfer for Typical Chemical Enamels.

These coefficients are of course, only relative, and are dependent to a large extent on the amount of agitation of the contained materials. Good agitation may increase values by as much as 20 to 25 per cent. Abbreviations: K is in B. T. U.s per sq. ft. per hour per °F. of temperature difference. K_1 refers to the heat transfer from steam to water being heated, while K_2 refers to the heat transfer from steam to boiling water.

1. Dry dust enamel for very severe chemical service.
   (a) Pfaudler No. 17, $K_1 = 60$; $K_2 = 80$
   (b) Pfaudler No. 11, $K_1 = 50$; $K_2 = 70$
2. Spray enamel for organic acids and less corrosive mineral acids.
   (a) Pfaudler No. 71, $K_1 = 125$; $K_2 = 150$
3. Spray dust enamel for mineral acids in general storage service, usually for equipment of large capacities.
   (a) Pfaudler No. 186, $K_1 = 90$; $K_2 = 100$

(B) Other Physical and Mechanical Properties.

Such physical properties of enamel as the coefficient of expansion, tensile strength, etc., are generally meaningless unless considered in connection with the steel on which the lining is applied. Ability to withstand rapid thermal change is tested in an automatic machine by intermittently heating enamel plates to 450°F. and then dipping them into ice water. However, both temperature and corrosion conditions to be met in each service application should be definitely ascertained and this information supplied to the manufacturer.

CHEMICAL STONEWARE

Ultimate compressive strength	82,000–115,000 lbs./in.^{2}
Ultimate tensile strength	1,650–4,300 lbs./in.^{2}
Modulus of elasticity	$1.05-5.95\times10^6$ lbs./in.^{2}
Specific heat	0.2
Thermal conductivity	0.78–2.05 B.T.U./ft.^{3}
Linear expansion per °F.	$1.9-2.3\times10^{-6}$
Ultimate bending strength	5,900–12,500 lbs./in.^{2}

GLASS AND FUSED SILICA

These materials are marketed in the form of sheets, tubes and rods.

Properties	Boro-silicate glass	Fused silica, clear	Fused silica, opaque
Thickness	0.01 in and up	0.001 in. and up	0.005 in and up
Transparency, T= Transparent, TL= Translucent, O= Opaque	T, TL	T	TL, O
Specific gravity	2.24	2.20	2.07–2.1
Specific volume, in.^{3}/lb.	12.3	12.6	13.4
Tensile strength, lbs./in.^{2}	93×10^5	$105-126\times10^5$	$94-114\times10^5$
Hardness, 2.5 mm. ball, 25 kg. load, depth in millimeters	0.015	0.0245	.....
Thermal expansion, per °C.	0.32×10^{-5} (0–300°C.)	0.049×10^{-5}	$0.053-0.059\times10^{-5}$
Thermal conductivity, cal./sec. cm.°C.	27×10^{-4}	23.7×10^{-4}	$19-20\times10^{-4}$
Specific heat, cal./°C. gram.	0.20	.....	.....
Softening point	1,290°F.	2,600°F.	2,600–2,700°F.
Breakdown voltage, 60 cycle, volts per mil.	1,400 (0.1 in. sample)	410 (¼ in.)	436 (¼ in.)
Dielectric constant, 60 cycle	4.86	3.7	3.7
Refractive index, N_D	1.47	1.459	.....

PROPERTIES OF MATERIALS OF CONSTRUCTION

PROPERTIES OF COKE BASE CARBON

Specific gravity	2.00–2.15
Apparent density	1.42–1.65
Porosity, %	25–30
Tensile strength, lbs./in.²	600–650
Crushing strength, lbs./in.²	5500–9000
Transverse strength, lbs./in.²	2000–6000
Thermal conductivity, cal./cm./°C.	0.007–0.008
Coef. of ther. expan., °C. (100–150°C.)	1.5–2 × 10^{-6}
Specific heat, cal./gm./°C. (26–282°C.)	0.200–0.250
Volatilization point, °F.	6,300–6700
Ash, %	0.5–10.0
Start of oxidation, °F.	625–840
Machining qualities	Good
Available in	Rod, tube, brick, plates, shapes

PROPERTIES OF HARD AND SOFT RUBBER *

Property	Hard rubber	Soft rubber	Linings
Specific gravity	1.12–2	0.97–1.25	0.98–1.35
Tensile strength, lbs./in.²	1000–10000	525–600	.....
Transverse strength, lbs./in.²	9000–15000	.....	.....
Compression strength, lbs./in.²	2000–15000	.....	.....
Hardness, scleroscope	50–80	.....	.....
Max. temp. for use, °F.	130–160	150–200	190
Effect of heat	Softens	Softens	Softens
Coef. of linear expansion, 32–140°F.	0.000035	0.000036	.....
Coef. of heat cond., K in B.T.U.s/ft.²in.°F.	1.07	1.07	.....
Resistance to abrasion	.....	20 times steel	.....
Resistance to tear, lbs./in.²	.....	15–80	.....
Dielectric strength, volts/mm.	25000–40000	25000–40000	.....
Effect of sunlight	Slight discoloration	Cracks	Ages
Effect of aging	Nil	Slight	Tendency to harden at normal temp.
Machining qualities	Good	Can be ground	.....
Available forms	Pipe and fittings, tank and pipe linings, misc. forms	Tank linings, hose, misc. forms	Tank, vat, pipe, valve linings for chemical and abrasive protection

VULCANIZED FIBER

Marketed forms	Sheets, tubes and rods
Thickness	0.004 and up
Forming properties	Good
Machining qualities	Good
Colors	Red, brown, white, gray, black, olive
Effect of heat	Stable to charring
Effect of water	Swells and softens. Warps on drying. Not recommended.
Effect of mineral, animal, and vegetable oils	Very slight absorption
Specific gravity	1.2–1.5
Specific volume	18.5–23 in.³/lb.
Tensile strength	8000–16000 lbs./in.²
Breakdown voltage, 60 cycle, $\frac{1}{16}$ inch sample	175–500 volts/mil

* See section on synthetic rubbers.

PROPERTIES OF MATERIALS OF CONSTRUCTION

ACID RESISTANT CEMENTS

For Brick, Metal, Earthenware, Stoneware, and Fused Silica.

	"Acid proof Cement No. 1" Quigley Co., Inc., New York, N.Y.	"Acid proof Cement No. 2" Quigley Co., Inc.	"Acipruf" Chemical Construction Corp., Charlotte, N.C.	"Basolit" Nukem Products Corp., Niagara Falls, N.Y.
Used for	Brick, for chimneys and flues	Brick and tile tank settings, chemical stoneware, fused silica	Brick, chemical and terracotta stoneware, rigid joints	Brick, porcelain, metal, chemical and terracotta stoneware, rigid joints
Composition	.....	....	.....	Silica-sulfur
Preparation for use	Ready mixed	Ready mixed	Mix with sodium silicate	Heat to 300°F. and pour
How applied	Trowel or dip bricks	Trowel	Trowel, with thin joints. For bell-and-spigot joints, press over asbestos rope	Pour into joints, with or without asbestos rope packing
Resistant to	Hot acid gases	Mineral acids	Mineral acids	Acids, fumes
Temperature range	To 2400°F.	To 1200°F.	To above boiling points of strongest acids	To 200°F.

	"Calktite" U.S. Stoneware Co., Akron, O.	"Carolina" Charlotte Chem. Labs. Inc., Charlotte, N.C.	"Chemical Putty" Charlotte Chem. Labs. Inc., Charlotte, N.C.	"Duralute" U.S. Stoneware Co., Akron, O.
Used for	Brick, bell-and-spigot joints on chemical stoneware	Brick, chemical and terracotta stoneware, rigid joints	Chemical stoneware, fused silica, Duriron, non-rigid joints	Brick
Composition	Asphaltic base	.....	Asbestos base	Asphaltic base
Preparation for use	Heat and pour	Ready mixed	Ready mixed	Heat and pour
How Applied	Pour into brick joints. For stoneware, pour over tamped asbestos wicking	Trowel with thin joints. For bell-and spigot joints, press over asbestos rope.	Press into joints	Pour into brick joints
Resistant to	Acids	Mineral acids	Mineral acids	Acids, alkalis
Temperature range	To 200°F.	To above boiling points of strongest acids	To 250°F.	To 200°F.

	"Duro" Special. Electrochemical Supply and Engineering Co., Paoli, Pa.	"Duro" Standard. Electrochem. Supply and Engrg. Co., Paoli, Pa.	"M.A. Knight Acid proof" Maurice A. Knight, Akron, O.	"Portite" U. S. Stoneware Co., Akron, O.
Used for	Brick, metal, glass, stoneware, earthware, fused silica, bell-and-spigot joint	Brick, metal, earthenware, chemical stoneware, fused silica glass	Brick, chemical stoneware	Brick
Composition	.....	.....	.....	Asphaltic base

PROPERTIES OF MATERIALS OF CONSTRUCTION

ACID RESISTANT CEMENTS

	"Duro" Special Electrochemical Supply and EngineeringCo.,Paoli, Pa.	"Duro" Standard Electrochem. Supply and Engrg.Co., Paoli, Pa.	"M. A. Knight Acid proof" Maurice A. Knight, Akron, O.	"Portite" U.S. Stoneware Co., Akron, O
Preparation for use	Mix two ingredients to consistency of thin putty	Mix two ingredients to consistency of thin putty	Mix with sodium silicate to the consistency of cream	Heat and pour
How applied	Trowel, joints thin or thick as desired. Heat to hasten drying	Trowel, thin joints. Heat surfaces before or after joining to hasten drying	Heat bricks to about 150°F. Lay with thin joints	Pour into brick joints
Resistant to	Weak acids, salts, fumes	Strong mineral acids, fumes	Acids	Acids
Temperature range	To 1500°F.	To 1500°F.	To 360°F.	To 200°F.

	"Mineralead" Atlas Mineral Products Co., Merztown,Pa.	"Pre-Mixt" U.S.Stoneware Co. Akron, O.	"S" Brand Silicate Philadelphia Quartz Co., Philadelphia, Pa.	"Thiogrout" Electrochemical Supply and Engineering Co., Paoli, Pa.
Used for	Cast iron	Brick	Brick	Bell-and-spigot joints
Composition	Sulfur base	.....	50 quartz, 20 mesh; 50quartz, 100 mesh; 70-100 "S" Brand Silicate	Sulfur base
Preparation for Use	Heat to 270-280°F. and pour	Mix with water to consistency of heavy cream	Mix to consistency of thick cream	Melt and pour
How applied	Pour over jute caulking	Bricks should be warm. Lay with thin joints	Dip bricks, lay with thinnest possible joints	Pack joint with asbestos rope and pour on cement
Resistant to	Solutions with pH under 7	Acids, neutral solutions	Acids, fumes	Weak acids, salts
Temperature range	To 200°F.	To 600°F.	.....	To 220°F.

	"U.S.Standard" U.S.Stoneware Co., Akron, O.	"Vitric-10" U.S. Stoneware Co., Akron, O.	"Vitrite-15" U. S. Stoneware Co., Akron, O.	"Vitrobond" Atlas Mineral Product Co., Merztown, Pa.
Used for	Brick	Brick	Brick	Brick, tile
Composition	.....	.....	.....	Sulfur base
Preparation for use	Mix with sodium silicate to consistency of heavy cream	Mix with sodium silicate to consistency of heavy cream	Mix with sodium silicate to consistency of heavy cream	Heat to 265°F. and pour
How applied	Bricks should be warm. Lay with thin joints	Bricks should be warm. Lay with thin joints	Bricks should be warm. Lay with thin joints	Pour into joints
Resistant to	Acids	Acids	Acids	Acids
Temperature range	To 350°F.	To 500°F.	To 500°F.	To 212°F.

7	Asbestos paper	With imbedded sponge particles 40 laminations per in.	Pipe covering and blocks
8	Asbestos paper products	Corrugated air cell type	Pipe covering and sheets
9	Asbestos paper, vitrified	Asbestos paper-treated with vitrifying solution and baked	Pipe covering and sheets
10	Bauxite, monohydrated	Molded with asbestos and clay	Pipe cov.-blocks and bricks
11	Cattle hair	Hair-felted	Blanket flexible
12	Cattle hair	Hair-felted	Blanket flexible
13	Cattle hair and jute	Hair and jute felted	Blanket flexible
14	Cattle hair and other fiber	Confined with building paper	Blanket flexible
15	Corkboard	No artificial binder	Pressed rigid slabs
16	Diatomaceous earth and clay, calcined	Molded and fired	Bricks
17	Diatomaceous earth blocks	Molded with asbestos, magnesia and clay	Pipe covering and blocks
18	Diatomaceous earth bricks	Natural brick cut from earth, heat flow $\perp$ to strata	Brick
19	Diatomaceous earth, calcined	Molded and fired	Bricks
20	Diatomaceous earth cements	Mixed with asbestos, magnesia and clay	Cement
21	Diatomaceous earth fillers	Coarse powder	Filler
22	Diatomaceous earth fillers	Fine powder	Filler
23	Fire felt	Long brown asbestos fiber and sodium silicate	Pipe covering and blocks
24	Fire felt	Short white asbestos fiber and sodium silicate	Pipe covering and sheets
25	Insulating boards	Pressed wood pulp	Rigid slabs
26	Insulating boards	Bagasse fiber	Rigid slabs
27	Insulating boards	Licorice roots	Rigid slabs
28	Insulating boards	Pressed wheat straw pulp	Rigid slabs
29	Kapok fiber	Tightly packed	Flexible
30	Magnesia	85% magnesia—15% asbestos	Pipe covering and blocks
31	Portland cement and calcined diatomaceous earth	Mixture of 4 pts. calcined earth to 1 pt. cement by volume	Poured as concrete
32	Rock cork	Rock wool and asphalt binder	Rigid slabs
33	Rock wool	Felted	Blankets
34	Rock wool	Felted with metal jacket	Pipe covering
35	Rock wool	Granulated	Filling
36	Rock wool	Loose	Filling
37	Rock wool	Molded with clay and asbestos	Sheets
38	Rock wool cement	Rock wool and clay	Cement
39	Sheetrock	Gypsum and sawdust	Rigid sheet between heavy papers

PROPERTIES OF MATERIALS
PHYSICAL AND THERMAL PROPERTIES

No.	Material	General composition	Commercial construction
1	Spun glass	Fine glass fibers, ⊥ to heat flow	Blanket
2	Thermax	Shredded wool and cement	Rigid sheet
3	Wool paper and hair	Laminated	Pipe covering
4	Wool paper products	Laminated wool felt	Solid pipe covering
5	Wool paper products	Indented wool felt	Pipe covering
6	Wool paper products	Wool paper and asphalt saturated paper—alternated	Pipe covering

†Changed to conform to new standards, effective Jan. 1, 1925.

These Drilling Templates are in multiples of four, so that fittings may be made to face in any quarter, and bolt holes straddle the center line. For bolts smaller than 1¾ inches the bolt holes shall be drilled ⅛ inch larger in diameter than the nominal diameter of the bolt. Holes for bolts 1¾ inches and larger shall be drilled ¼ inch larger than nominal diameter of bolts. The bolt holes on cast iron flanged fittings are not spot faced for ordinary service. When required, the fittings and flanges in sizes 36 inches and larger can be spot faced or back faced, so that standard length bolts can be used. All 125 lb. cast iron standard flanges have a plain face.

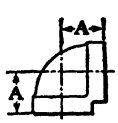
The bolt holes on cast iron flanged fittings are not spot faced for ordinary service. When required, the fittings and flanges in sizes 36 inches and larger can be spot faced or back faced so that standard length bolts can be used.

All 250 pound standard flanges have a ⅛ inch raised face. This raised face is included in the face to face, center to face and the minimum thickness of flange dimensions.



†These sizes are special.

FLOW OF WATER IN CAST IRON PIPE

(From Pipe Economy, 8th Ed., James B. Clow and Sons, publishers, by permission.)

In attempting to compute the capacity of a pipe line or to figure the probable loss in head, after the pipe has reached a certain age, it is absolutely essential to know something about the water to be conveyed. In most cases the quality of the water is such that the carrying capacity is affected very little by the age of the pipe. In other cases, the water may be so soft as to cause tuberculation and consequent loss in carrying capacity or so turbid as to cause deposits of sand or mud with the same effect. Waters that cause tuberculation are the rare exception and outside of a few raw water conduits, muddy water is also unusual.

In spite of this fact, many of the books and articles on hydraulics and water supply, make the bold statement that a definite correction factor must be applied to flow formulae as the pipe increases in age. It is evident that this is incorrect, since first of all a large number of experiments have been made that show quite definitely that in many places there is no change whatever in carrying capacity with age. Secondly, assume that a layer of tubercles 2 inches thick are produced as a result of many years use of a pipe, it is evident that the carrying capacity of a 12 inch pipe would be considerably more reduced than would a 48 inch pipe with the same thickness of tubercles, a fact that is not taken into consideration in the formulae in common use.

In presenting the flow tables, that follow, we are giving the values for new pipe. In most cases, it can be told beforehand whether or not the water to be conveyed will cause tuberculation. If tuberculation is not to be expected, ordinary Cast Iron Pipe should be used and the carrying capacity figured as shown in the tables. If it is known beforehand, the water is of such a nature as to cause tuberculation, cement lined Cast Iron Pipe should be used and, as in

previous case, the tables used without any correction factor.

The following tables represent the Flow of Water through Clean Cast Iron Pipe computed by the Formula derived after careful investigation by Edward Wegmann, C. E.[1] and Albert N. Aeryns, C. E.[2] The Wegmann-Aeryns Formula, which appeared in the Engineering News-Record for July 16, 1925, is as follows:

$$V = 182.5\ R^{0.723}\ S^{0.539}$$

in which

V = Velocity in feet per second
R = Hydraulic radius in feet
S = Slope of the hydraulic gradient, or loss of head in feet per foot of pipe.

It should be remembered that the "loss of head," or friction head, given in feet per thousand feet of length, is also the fall in feet per thousand (the slope) required to produce the given velocity in pipe of the diameter given. The following examples illustrate the various uses of the table:

EXAMPLE 1. MAXIMUM DELIVERY

To find the maximum delivery of an 8-inch pipe, 7,500 feet long under 150 foot head. The available head per thousand feet is 150 ÷ 7.5 = 20 feet per thousand. The table for 8-inch pipe, under "loss of head," shows that for a loss of head of 15.7 feet per thousand the corresponding delivery at velocity of 5.32 feet per second is 1,200,000 gallons per day; the approximate value for a loss of 20 feet may then be calculated by interpolation.

EXAMPLE 2. DETERMINATION OF DIAMETER

To find diameter of pipe necessary to deliver 3,000,000 gallons per day through a line 25,000 feet long under 150 foot head. The available head per thousand feet is 150 ÷ 25 = 6 feet per thousand. Reading across table from discharge of 3,000,000 gallons, at the left, the first "loss of head" of 6 feet or less per thousand is 5.1 under 14-inch pipe. Hence the least diameter which will answer in regular commercial sizes is 14 inches.

EXAMPLE 3. FRICTION LOSS

To find loss of head through a 10-inch line, 4,000 feet long delivering 1,000 gallons per minute. The table shows "loss of head" in a 10-inch pipe delivering 972 gallons per minute to be 6.8 feet per 1,000 feet of length; hence in 4,000 feet the loss will be 27.2 feet. If the water is delivered at a point 100 feet above pump, the total head pumped against is 100 feet (static) plus 27.2 feet (friction), or 127.2 feet total.

EXAMPLE 4. DELIVERY DETERMINED FROM PRESSURE REDUCTION

Two accurate pressure gauges should be placed at a known distance apart, and measurement made of the difference in elevation of the points where readings are taken; thus, if in a 12-inch pipe the gauges are 500 feet apart and show a difference in pressure of 2 pounds (4.6 feet) while one gauge is 1.8 feet above the other, the actual loss of head will be 4.6 plus or minus 1.8 = 6.4 or 2.8 feet per 500 feet, or 12.8 or 5.6 feet per thousand feet. In the table for 12-inch pipe we find that a loss of head of 5.2 feet per thousand is due to velocity of 3.94 corresponding to discharge of 2,000,000 gallons per day.

EXAMPLE 5. TO FIND THE PRESSURE

To find the pressure at any point in a water main when diameter, rate of delivery and static head are known. Assume that 1,200,000 gallons per day are to be pumped through 5,000 feet of 12-inch pipe laid on an incline to a total vertical height of 100 feet and that it is desired to learn the pressure in the pipe at each 1,000 feet from the pump. At the given delivery the loss of head in a 12-inch pipe is 2.0 per 1,000 feet or 10.0 for 5,000 feet; to this is added the static head, making total of 110 feet. The drop in pressure for each 1,000 feet will then be one-fifth of this quantity or 22 feet.

(See table on the next page)

FLOW OF WATER IN CAST IRON PIPE

Frictional Heads, per Thousand Feet, at Given Rates of Discharge

(From Cameron Hydraulic Data, 9th Ed., 1934, Ingersoll-Rand Co., publishers, by permission.)

The tables on the following pages may be used for all liquids having a viscosity equal to that of water. The head loss will read in feet of the liquid regardless of its specific gravity. The values are those calculated for cast iron pipe. Where other types of pipe are being employed the head loss in the tables must be multiplied by a suitable factor in order to correct them. These correction factors are:

0.54 for very smooth and straight wrought iron, brass or tin pipe.
0.64 for copper tubing, ordinary straight brass or tin pipe.
0.71 for smooth wrought iron pipe.
0.84 for spiral riveted steel pipe (flow with lap).
1.00 for cast iron pipe; spiral riveted steel pipe (flow against lap).

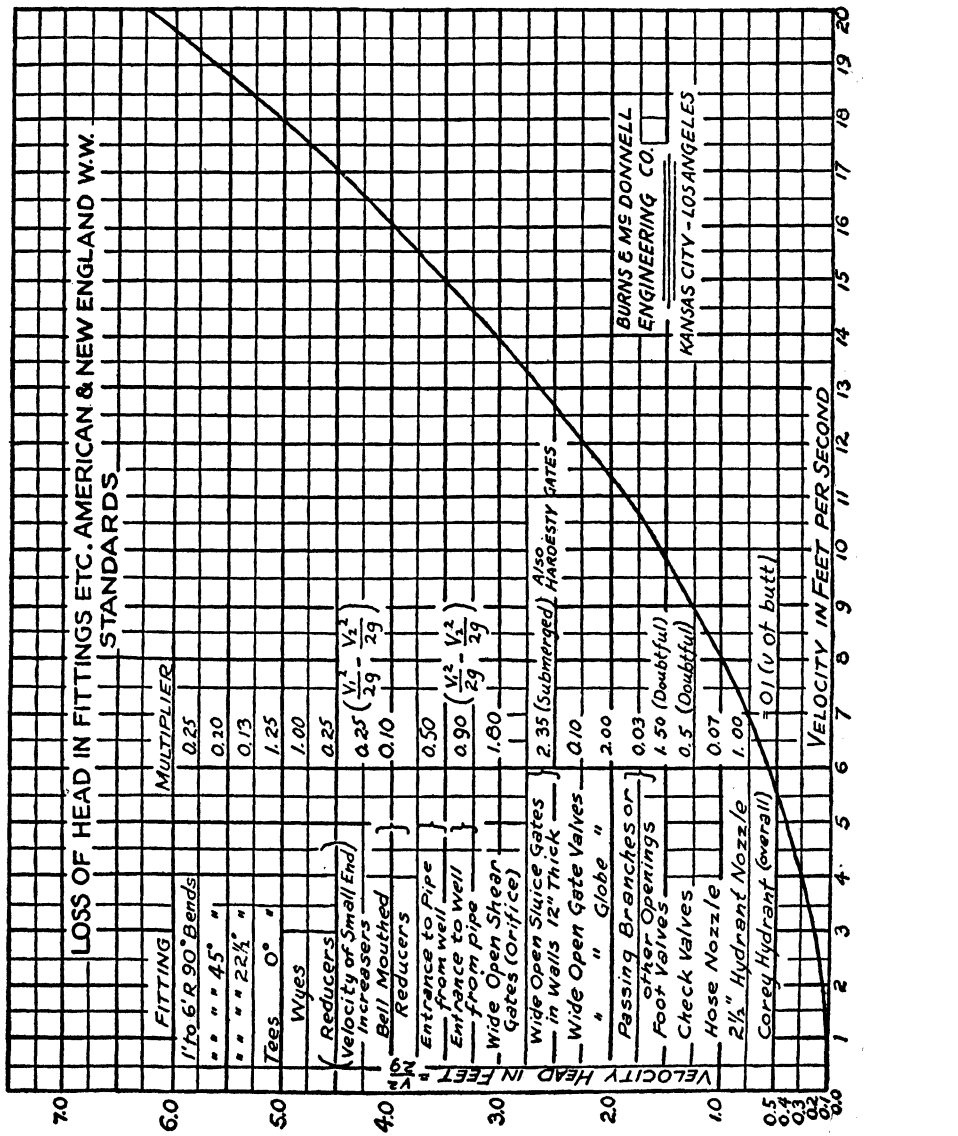
Right-hand column, Relative Flow Capacity, is based on arbitrary of 1.0 for 12-inch pipe.



Calculations for above table based on assumption that relative deliveries at same loss of head are to each other as 5/2 power of the respective diameters.

Illustrative Example: How many 10-inch pipe will equal in total flow one 36-inch pipe?

Reading horizontally from 36 to intersection, table shows 24.6 10-inch pipe required—or, in practice, 25. Similarly 10 12-inch pipe =1 30-inch pipe.

LOSS OF HEAD IN FITTINGS

(From Pipe Economy, 8th Ed., James B. Clow and Sons, publishers, by permission.)

DISCHARGE OF GAS IN CUBIC FEET PER HOUR, THROUGH PIPE OF DIFFERENT DIAMETERS AND VARIOUS LENGTHS, IN LINEAR YARDS

Pressure of Water in Inches, 1, 1.5, 2, 2.5. Specific Gravity, 0.400

(From Pipe Economy, 8th Ed., James B. Clow and Sons, publishers, by permission.)

Above tables computed by Dr. Pole's formula:

$$Q = 1350\, D^2 \sqrt{\frac{HD}{GL}} \qquad D = 0.056 \sqrt[5]{\frac{Q^2GL}{H}}$$

in which

Q = quantity of gas, cubic feet per hour
D = diameter of pipe, inches
H = pressure by head of water in inches
L = length of pipe, linear yards
G = specific gravity of gas (taken as 0.400)

For other values of G, multiply quantities given in table by square root of .4 and divide by square root of new value. For lengths one-fourth those in table, discharge of gas is doubled; for lengths four times greater than table, the discharge equals one-half of quantities in table.

Four times the pressure doubles the discharge.

FLOW MEASUREMENT

From Information Furnished by Members of the Technical Staff of
The Bailey Meter Co., Cleveland, Ohio

Nomenclature.—

C = Coefficient of Discharge; unit: a ratio.
W_h = Rate of flow; unit: pounds per hour.
ρ = Density of flowing fluid; unit: pounds per cubic foot.
ρ'_f = Density of dry air at 29.92 inches of mercury pressure and at the actual (experimental) temperature; unit: pounds per cubic foot.
ρ'_a = Density of saturated steam vapor at 60°F.; unit: pounds per cubic foot.
G_f = Specific gravity of air or gas under actual (experimental) conditions referred to air at 29.92 inches of mercury pressure and 60°F. as unity; unit: a ratio.
H = Differential head; unit: inches of water.
H_1 = Differential head; unit: inches of mercury.
h = Differential head; unit: inches of flowing fluid.
d_1 = Diameter of pipe; unit: inches.
d_2 = Diameter of orifice; unit: inches.
S = Saturation of air or gas mixture with moisture in per cent divided by 100, under actual (experimental) conditions.
p'_f = Pressure of saturated steam at actual (experimental) temperature; unit: inches of mercury.
p_f = Observed absolute pressure (equal to barometric reading plus gage reading in inches of mercury); unit: inches of mercury.

One of the most convenient methods for measuring the flow of fluids through a conduit, is by means of a head meter. In the head meter, a primary element is placed in the flowing fluid to produce a pressure difference or *differential head* which the secondary element then uses as an indication of the rate of flow. The primary element produces the differential head either by constricting the flow (orifice, venturi tube, flow nozzle, weir, etc.) or by measuring the impact of the flowing fluid (pitot tube). The secondary element consists of some form of manometer for measuring the differential head produced by the primary element.

If the flow is to be measured accurately, the flowing fluid must be free from turbulence, such as would be produced by obstructions and bends in the piping too near the orifice location, and must not be a pulsating flow as would be produced by reciprocating engines, pumps, and certain types of blowers. The flowing fluid must also be non-viscous unless corrections are applied, corrections which are beyond the scope of this short presentation. In general, at least, a length equal to 20 diameters of straight pipe without valves or fittings should precede the primary element location.

Manometers.—Manometers usually consist of two glass tubes connected at the bottom. The differential pressures are connected to the tops of the glass tubes. The glass tubes are usually filled half full with a liquid and the difference between the levels will give the *differential*. Liquids commonly used in manometers are: water (sp. gr. 1.00); carbon tetrachloride (sp. gr. 1.60); acetylene tetrabromide (sp. gr. 2.96); and mercury (sp. gr. 13.56). Since differentials are usually expressed in inches of water, it is necessary to convert measurements with other liquids to the corresponding head of water. This is done by multiplying the differential head of the liquid by its specific gravity. If the liquid in the gauge is under a column of the liquid whose flow is being measured, the specific gravity of the flowing liquid must be subtracted from the specific gravity of the gage liquid. If, for example, the flow of water (sp. gr. = 1) is being measured by a mercury manometer (sp. gr. = 13.56), then

$$H_1(13.56-1) = H$$

The weight of gases can usually be neglected except at high pressures.

Orifices.—One of the simplest of

the primary elements used to produce a throttling action is the *orifice plate.* It consists of a thin disc of stainless steel or monel metal in the center of which is a hole smaller in diameter than the inside of the pipe with which it is to be used. The maximum reduction in pressure produced by this throttling action is at a point, downstream from the orifice plate, called the *vena contracta.* The position of the vena contracta with a given orifice is practically the same for all rates of flow. Since the pressure is partially restored after passing the vena contracta, it is desirable to make the downstream connection to the manometer as near the vena contracta as possible.

The outside diameter of the orifice plate should fit snugly inside the bolt circle of the pipe flange so that the orifice hole will be concentric with respect to the pipe diameter. For use in pipes of six inches or less in diameter, the orifice plate should be $\frac{1}{16}$ inch in thickness; for pipe diameters from 6 inches up to 15 inches the orifice plate should be at least $\frac{1}{8}$ inch in thickness. It is essential that the inside of the orifice hole be smooth and free from burrs. The upstream edge must be sharp and square, and the downstream side should have a 45° bevel to $\frac{1}{32}$ inch edge thickness.

The connections to the orifice should be made by means of $\frac{1}{2}$ inch pipe nipples. These nipples should be filed flush with the inside of the pipe and must, under no conditions, project into the flowing stream. The upstream connection should be made about one pipe diameter from the orifice plate. The downstream connection should be at the vena contracta. If an easily condensed gas or vapor (e. g., steam) is being measured, a reservoir for collecting condensate (water) must be placed on each nipple. Each reservoir should hold about 20 or 30 cubic inches of condensed liquid, and these reservoirs must be so mounted that the liquid level is exactly at the same height in both, otherwise a false differential will be created.

Selection and Calculation of the Proper Size of Orifice.—The general formula for calculating orifices is:

$$W_h = 360 \times (d_2)^2 \times C \sqrt{\frac{H\rho}{1-\left(\frac{d_2}{d_1}\right)^4}}$$

These formulas do not take into account the compressibility of the gas nor the thermal expansion of the orifice plate but are sufficiently accurate for most practical applications. Since W_h, d_2, and H are variables, it is necessary to assign values to two of these factors in order to solve the equation. The diameter of the orifice hole d_2 is usually selected so as to give the maximum H when the flow W_h is at the maximum. H is, therefore, selected before starting the design of the orifice. It is desirable to make H as large as practical for more accurate reading if the differential is to be read by means of a U-tube manometer. If a flow meter is to be used, the H will usually be the maximum head for which the flow meter is designed. H is also limited in some instances by the pressure loss that can be tolerated, as is the case when measuring flows under low pressures. The pressure loss due to the orifice may be calculated from curve No. 3 on per cent differential head lost.

The most practical method for calculating an orifice is by trial since it eliminates solving a fourth degree equation. A value for d_2 is arbitrarily chosen, then from the orifice ratio d_2/d_1, a value for C is found from curves No. 2 on discharge coefficients. These values are then placed in the equation and the equation is solved for W_h. If an approximate value for the maximum flow through the pipe line is known, the value for d_2 is altered until the desired value for W_h is secured.

When the orifice is in operation, of course, the values for d_1, d_2, C, and ρ are constant so long as the state of the fluid does not differ from that for which the orifice was designed. These factors are then multiplied together to give a new constant by which the instantaneous value for H as read from the manometer or meter may be multiplied to give the rate of flow per hour at that instant. This is done by writing equation No. 1 (see below) in this form:

FLOW MEASUREMENT

$$W_h = \left[(360) \times (d_2)^2 \times (C) \times \sqrt{\frac{1}{1-\left(\frac{d_2}{d_1}\right)^4}} \times \sqrt{\rho} \right] \times \sqrt{H}$$

The terms enclosed within the brackets being the constant for the orifice.

The desirability for designing an orifice to give the maximum differential head will be appreciated when it is realized that the differential head developed by a flow through an orifice is a square root relationship, so that if an orifice, for example, has twice the necessary capacity, it will develop only one-fourth the head otherwise obtainable. If no estimate of the maximum flow is available, it may be necessary to design and build a trial orifice and from trial tests run with this orifice sufficient data can be secured from which an orifice of correct proportions can be designed.

Example.—The flow of water through a 6 inch pipe is estimated to be 180,000 pounds per hour. What should be the diameter of the orifice hole if used with a 10 inch manometer? Where should the downstream tap be located? What is the pressure loss due to the orifice at maximum flow? What is the flow through the 6 inch pipe when an orifice, designed for the conditions mentioned above, produces a 5 inch differential on the mercury manometer? The water (sp. gr. =1) to be measured is at a temperature of 60°F., and therefore $\rho = 62.4$; the manometer to be used has a maximum range of 10 inches of mercury (sp. gr. 13.56), or $H = 10(13.56-1) = 125.6$ inches of water.

For a trial a 3 inch orifice hole may be assumed. The ratio, d_2/d_1, will then be 3.00/6.00 = 0.50. From curve No. 2 it will be found that for a 0.50 ratio and a 6 inch pipe, C is 0.608. These values are then substituted in equation No. 1, and grouping the values which are constants gives the following:

$$W_h = \left[(360) \times (3)^2 \times (0.608) \sqrt{\frac{1}{1-\left(\frac{3.00}{6.00}\right)^4}} \times \sqrt{62.4} \right] \times \sqrt{125.6}$$

$$= 16{,}100 \times \sqrt{125.6}$$

$$= 180{,}100 \text{ pounds per hour.}$$

From curve No. 1 it will be found that for a 0.50 ratio, the downstream connection should be 0.6 diameters from the orifice plate to bring its position at the middle of the vena contracta; *i. e.*, $0.6 \times 6 = 3.6$ inches, and the minimum distance allowable is $0.4 \times 6 = 2.4$ inches, and the maximum distance allowable is $0.75 \times 6 = 4.5$ inches.

The pressure loss due to the orifice is calculated by multiplying H by a constant as read from curve No. 3. Thus, in the example given above, the pressure lost with a 0.50 ratio is 0.72 of the head which at the maximum flow is: $(0.72) \times (125.6) = 90.5$ inches of water, or since (inches of water) $\div 27.72$ = pounds per square inch, the pressure loss due to the orifice when 180,000 pounds per hour is flowing through the pipe will be: $90.5 \div 27.72 = 3.26$ pounds per square inch.

The rate of flow for 5 inches of mercury differential is calculated as follows:

$$H = 5 \times (13.56-1) = 62.8 \text{ inches of water}$$

$$W_h = 16{,}100 \times \sqrt{62.8}$$

$$= 127{,}400 \text{ pounds per hour.}$$

ORIFICE FORMULAS

For liquids:

(1) $$W_h = (360) \times (d_2)^2 \times (C) \times \sqrt{\frac{(\rho) \times (H)}{1-\left(\frac{d_2}{d_1}\right)^4}}$$

For dry gases under actual (experimental) conditions of temperature and pressure:

(2) $$W_h = (360) \times (d_2)^2 \times (C) \times \sqrt{\frac{(\rho_f)\ (G_f)\ (H)}{1-\left(\frac{d_2}{d_1}\right)^4}}$$

For wet gases under actual (experimental) conditions of temperature and pressure:

(3) $$W_h = (360) \times (d_2)^2 \times (C) \times \sqrt{\frac{[\rho'_f \times G_f (p_f - p'_f) + (\rho'_a)\ (S)]\, H}{1-\left(\frac{d_2}{d_1}\right)^4}}$$

PITOT TUBE FORMULAS

Two common types of pitot tubes are the *combined impact reverse*, and the *combined impact static*. In the combined impact reverse one opening faces upstream and the other opening downstream. In the combined impact

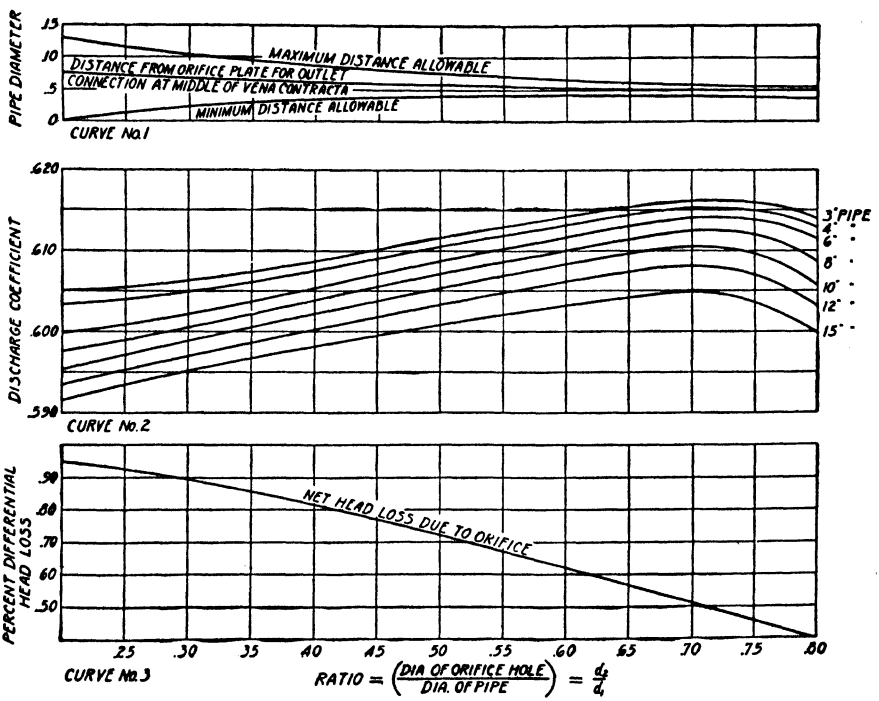
PITOT TUBE FORMULAS

static one opening faces upstream and the second opening faces normal to the direction of the flow.

Combined impact reverse type:

(4) $W_h = (255) \times (d_1)^2 \times \sqrt{(p) \times \left(\frac{h}{12}\right)}$

Combined impact static type:



(5) $W_h = (353) \times (d_1)^2 \times \sqrt{(p) \times \left(\frac{h}{12}\right)}$

V-NOTCH WEIR FORMULA

(6) $W_h = (1946) \times (C) \times \left(\tan \frac{\alpha}{2}\right) \times h^{2.48}$

The values of C (coefficient of discharge) for various angles of the notch (α) are:

when $\alpha = 30°$	then $C = 0.5930$
$= 45°$	$= 0.5820$
$= 60°$	$= 0.5785$
$= 75°$	$= 0.5785$
$= 90°$	$= 0.5815$

SUGGESTIONS ON DESIGN OF NICHROME HEATING ELEMENTS

Reprinted from Catalog R-28, Driver-Harris Company by Permission.

The table below gives the size of "Nichrome" suggested for a given number of watts at 110 volts. The sizes are selected to operate at approximately 1500°F. in open coils and are suitable for electric irons, toasters, hot plates, space heaters, etc.

NICHROME WIRE. 110 VOLTS

Watts	Amperes	B. & S. Size	Ohms 75° F	Length	
				21 Ft.	2 Ins.
250	2.27	25	43.6		
300	2.72	24	36.4	22	0
350	3.2	23	31.0	24	0
400	3.64	23	27.2	21	0
450	4.10	22	24.1	23	5
475	4.32	22	23.0	22	4
500	4.55	22	21.8	21	0
550	5.0	21	19.8	24	5
575	5.23	21	18.9	23	2
600	5.46	21	18.1	22	4
615	5.6	20	17.7	27	6
640	5.82	20	17.0	26	6
660	6.0	20	16.5	25	8
700	6.36	20	15.6	24	4
750	6.81	19	14.5	28	5

For voltages other than 110 divide the number of watts required at the given voltage by the voltage factor below. Select the nearest number of watts in the 110 volt table, multiply the length in 110 volt table by the voltage factor. Suppose an electric iron takes 550 watts and the supply voltage is 100. Factor for 100 volts is .91 and $\frac{550}{.91} = 605$ watts.

Nearest value in 110 volt table is 600 watts which requires 22′ 4″ of size 21 wire. This gives the size to be used on 110 volts, but the length should be 0.91×22′4″ or 20′4″. The winding for 550 watts, 100 volts would then be 20′4″ of size 21 "Nichrome" wire.

VOLTAGE FACTORS ON BASIS OF 110 VOLTS

Voltage	100	120	150	200	220	240	32
Factor	.91	1.09	1.36	1.82	2.0	2.18	0.29

ADVANCE RESISTANCE WIRE

Reprinted from Catalog R-28, Driver-Harris Company by Permission.

Specific resistance 294 ohms per circular mil-foot at 20°C. (68°F.). The change of resistance with change of temperature is negligible. Thermal E. M. F. against copper is approximately 0.043 milli-volts per degree Centigrade, between 0°C. and 100°C.

TEMPERATURE CORRECTIONS

(Based on A. I. E. E. Standards)

Temperature Coefficient of Resistance. At a temperature of 25°C the constant mass" temperature coefficient of resistance of standard annealed copper, measured between potential points rigidly fixed to the wire is 0.00385 or 1/259.5 per Centigrade degree. Resistance values of copper wire given in tables at 25°C may be corrected for any temperature by means of the following formula— $Rt = R_{25}[1+0.00385(t-25)]$, where Rt is the resistance in ohms at a temperature t°C; R_{25} is the resistance in ohms at 25°C; and, t is the temperature of wire in degrees Centigrade.

STANDARD CALIBRATION TABLES FOR THERMOCOUPLES

The following tables represent arbitrary reference curves which show fairly well the relation between E. M. F. and temperature and consequently should be used with an appropriate correction curve which must be determined for any individual thermocouple by means of a calibration at three or more fixed temperature points. Such a correction curve is constructed by plotting ΔE the difference between the observed E. M. F. at a known temperature and the E. M. F. for this same temperature (as read from the table) against the standard E. M. F. given in the table. The corrected E. M. F. for any temperature is then obtained by subtracting algebraically ΔE as read from the correction curve from the observed E. M. F., before converting the latter into a temperature as read from the table. The tables which follow are for a fixed (or cold) junction maintained at 0°C. If this fixed junction is not at 0°C. but at some other temperature which is very near to 0°C. a correction should be applied as follows: $E_h = E_o + E$ where E_o is the observed E. M. F., E is the E. M. F. corresponding to the temperature of the fixed junction and E_h is the desired E. M. F. corrected for the temperature at which the fixed junction is being maintained. In the tables which follow the E. M. F. values are expressed in millivolts and the temperatures in degrees centigrade.

PLATINUM — PLATINUM (90%), RHODIUM (10%) THERMOCOUPLE

Standard range 630° — 1083°C; applicability range 0°—1754°C. Computed from values given in Int. Crit. Tables, Vol. 1, p. 57.

CHANGES IN CALIBRATION

Direct comparison with standard instruments or with a number of fixed points is more accurate than calibration between just a few fixed points over a wide range. Mercury and glass do not expand uniformly with rise in temperature the expansion accelerating with rise in temperature, and in the case of glass this varies with different varieties. Usually thermometers are calibrated for use in a vertical position and when such instruments are used in a horizontal position the readings are too high because of the difference in pressure exerted by the mercury column on the mercury contained in the bulb. This error (E), which is most pronounced with long thermometers, must be determined empirically at points along the temperature scale. For angles Θ (between the horizontal and vertical positions) the correction at the same temperature is $E \times \sin \Theta$. Thermometers are also subject to changes in readings caused by several conditions. Glass is subject to contraction over a number of years thus causing higher readings with lapse of time. After a thermometer has experienced a rise in temperature there is a lapse of time before the glass attains the volume corresponding to that temperature and if kept at a high temperature for long periods the ice point and the boiling point may be permanently lowered. Exposure to high temperatures for long periods may also cause a permanent change due to distillation of the mercury to the top of the stem, although this distillation is minimized with gas filled thermometers. Use of a thermometer in a vacuum may cause low readings. See also section on *Correction for Emergent Stem.*

CORRECTION FOR EMERGENT STEM OF LIQUID-IN-GLASS THERMOMETERS

When a thermometer which has been standardized for total immersion is used with a part of the liquid column at a temperature below that of the bulb, the reading is low and a correction must be applied. For this correction the following formula is employed.:

$$T_c = T_o + f \times l \times (T_o - T_m)$$

where T_c = corrected temperature

T_o = observed temperature

l = length of column in degrees above the surface of the liquid the temperature of which is being taken

T_m = mean temperature of mercury (or other thermometer liquid) column; i. e., the temperature of the middle point of the mercury (or other liquid) column as read from another thermometer

f = correction factor as given in the table below. In calculating the emergent stem correction for thermometers containing organic liquids (alcohol, pentane, toluene) it is sufficient to use the approximate value, $f = 0.001$. In such thermometers the value of f is practically independent of the kind of glass.

CORRECTION FACTORS FOR MERCURY-IN-GLASS THERMOMETERS

BOILING POINT CORRECTION

To correct for small differences in barometric pressure the following formula is employed:

$$T_c = T_o + 0.043\,(760 - P)$$

where T_c = corrected boiling point.

T_o = observed boiling point.

P = atmospheric pressure in millimeters of mercury.

CORRECTION OF BOILING POINT TEMPERATURE AT VARIOUS PRESSURES TO NORMAL PRESSURE (760 mm., 29.92 in. Hg)

CORRECTION OF BOILING POINT TEMPERATURE AT VARIOUS PRESSURES TO NORMAL PRESSURE (760 mm. Hg)

A. S. T. M. METHOD

In the *A. S. T. M. Standards on Petroleum Products and Lubricants*, September 1937, page 96, the Sydney Young equation is used for calculating the proper correction to the observed boiling point. In this equation the temperature range as well as the pressure is considered. The Sydney Young equation is as follows:

$$\text{For Centigrade scale: } C_c = 0.00012\ (760 - P)\ (273 + t_c),$$
$$\text{For Fahrenheit scale: } C_f = 0.00012\ (760 - P)\ (460 + t_f),$$

in which C_c and C_f are, respectively, corrections to be made on the observed temperatures t_c or t_f, and P is the actual barometric pressure in millimeters of mercury.

The table below is a convenient approximation of the corrections as calculated from the equations above. These approximations will suffice for ordinary work. For more precise work, the correction should be calculated using the Sydney Young equation and the temperature when 50% of the material has boiled. A new correction should be made for each variation of more than 10°C. or 18°F.

(Completed on following page.)

CORRECTION OF BOILING POINT TEMPERATURES

Boiling Point		Correction for Each One mm. Difference in Pressure*	
t_c in °C.	t_f in °F.	C_c in °C.	C_f in °F.
10–30	50–86	0.035	0.063
30–50	86–122	.038	.068

* To be added in case barometric pressure is below 760 mm., to be subtracted in case the pressure is above 760 mm.

CALCULATION OF BOILING POINTS OF ORGANIC COMPOUNDS

Cf. Kinney, *Jour. Am. Chem. Soc. 60, 3032 (1938); Ind. Eng. Chem. 32, 559 (1940).*

Boiling points of organic compounds may be calculated from their structures as follows: Obtain the molecular *B.P.N.* by adding together the appropriate boiling point numbers (*b.p.n.*) for the various atoms and structural groupings given in Table I. From the *B.P.N.* obtain the B.P. (boiling point in degrees Centigrade) using Table II.

Certain rules must be followed in applying the data:

1. The *b.p.n.'s* of 0.8 and 1.0 are applied to the carbon and hydrogen atoms, respectively, of the longest aliphatic chain in the molecule. It is essential that the longest aliphatic chain be used as the base because the boiling point is dependent, in part, upon this factor.
2. All groups or atoms attached to this chain are assigned *b.p.n.'s* as indicated in Table I.
3. With many atoms and groups the position of the group, or the presence of other groups, alters the *b.p.n.* These, as far as are known, are given in Table I.

Example: To calculate the boiling point of 1-methyl-4-(1-methylethyl)-1-cyclopentene, $(CH_3)_2$:CH·CH·CH_2·C(CH_3):CH·CH_2.

Carbon in the longest aliphatic chain (2× 0.8)	1.6
Hydrogen in the longest aliphatic chain (4× 1.0)	4.0
Methyl radical attached to the aliphatic chain	3.05
Carbon in the cyclopentene ring (5× 0.8)	4.0
Hydrogen in the cyclopentene ring (6×1.0)	6.0
B.P.N. for the 5-membered ring	2.5
B.P.N. for the ethylenic linkage, type R_2C:CHR	2.3
Methyl attached to the cyclopentene ring	3.05
Calculated *B.P.N.*, sum of the items above	26.50
Calculated B.P., from Table II	142.5°C.
Observed B.P.	143.1°C.

Example: To calculate the boiling point of 2,8-dimethyl-5-nonanone, $[(CH_3)_2CH\cdot CH_2\cdot CH_2]_2CO$.

Carbon in the longest aliphatic chain (9× 0.8)	7.2
Hydrogen in the longest aliphatic chain (16× 1.0)	16.0
Two methyl radicals (2× 3.05)	6.1
One carbonyl oxygen, type RCH_2COCH_2R	7.5
Calculated *B.P.N.*, sum of the items above	36.8
Calculated B.P., from Table II	222.5°C.
Observed B.P.	226.0°C.

TABLE I.

ATOMIC AND GROUP BOILING POINT NUMBERS.

Carbon, in the main chain	0.8	Type of olefinic linkage	
Hydrogen, attached to the main chain	1.0	CH_2=CH_2	1.2
		RCH=CH_2	1.5
Radicals, saturated, attached to the main chain or to cyclic rings		RCH=CHR	1.9
		R_2C=CHR	2.3
Methyl	3.05	R_2C=CR_2	2.8
Ethyl	5.5		
Propyl	7.0	Radicals, unsaturated, attached to main chain	
Butyl	9.7		
2,2-Dimethyl grouping	−0.4	Methylene	4.4
		Ethylidene	7.0
Two or three alkyls attached to adjacent carbons of saturated main chains of 6 carbons or less	+0.5	Vinyl	5.4
		Propylidene	9.0
		Butylidene	10.4
Four or more alkyls attached to adjacent carbons of saturated main chains of 6 carbons or less	+1.0	Type of acetylenic linkage	
		HC≡CH	4.0
		RC≡CH	4.4
		RC≡CCH_3	5.4
		RC≡CR	4.8

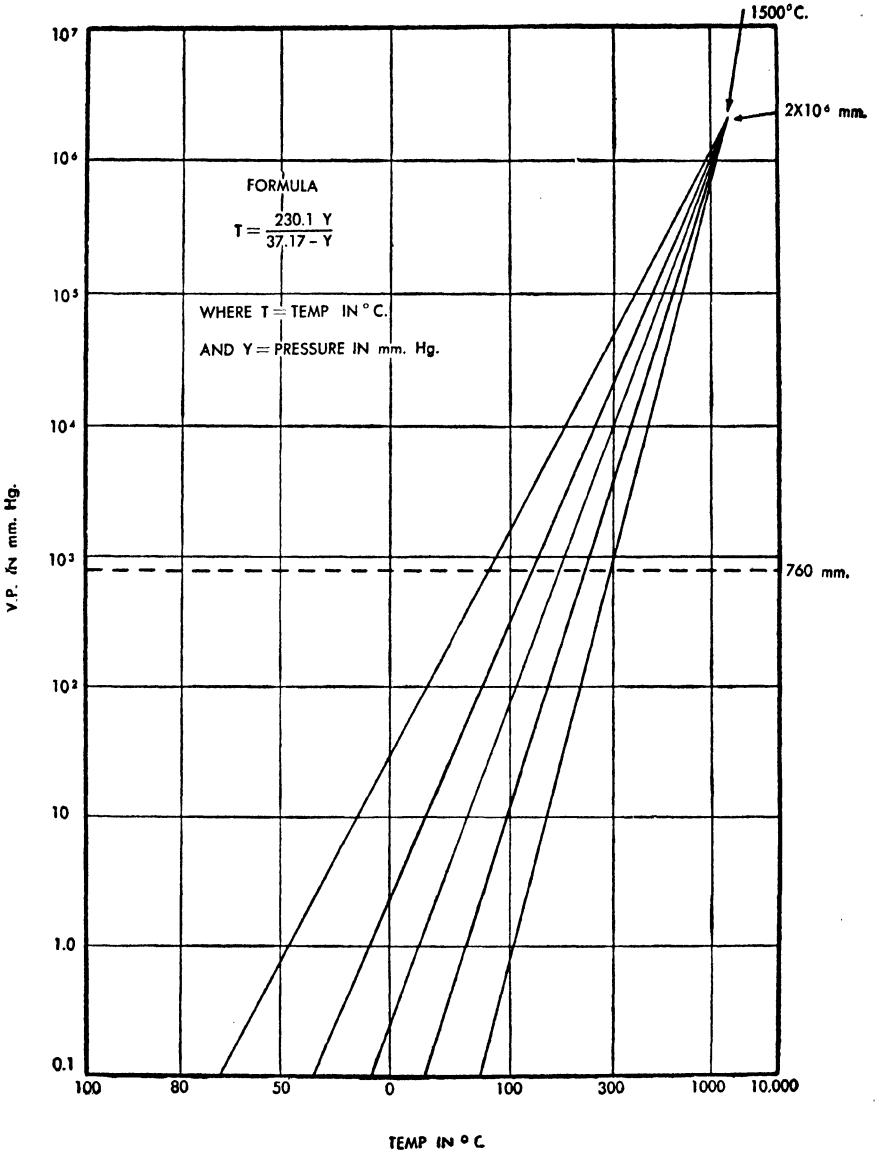
BOILING POINTS AT VARIOUS PRESSURES
COX CHART METHOD



Cf. Cox, *Ind. Eng. Chem. 15, 592 (1923)*; Davis, *ibid. 17, 735 (1925)*; Calingaert and Davis, *ibid. 17, 1287 (1925)*.

A Cox chart, of the family to which a compound belongs, may be used to obtain the boiling point at any pressure, or the vapor pressure at any temperature. By drawing a straight line through the boiling point at 760 mm. and the infinite point, a curve is obtained which gives the relationship between the temperature and the vapor pressure. To construct a Cox chart, the ordinates for pressure values are laid off logarithmically with the aid of a log scale on a slide rule. The formula $T = 230.1Y \div (37.17 - Y)$ is used for spacing of the temperature values on the abscissa. Drawn in this manner, a Cox chart can be applied to any family of compounds or to any single compound. The sample chart shown on the following page shows curves for the vapor pressures of five compounds belonging to the alkyl benzene family with the infinite point at 1500°C. and 2×10^6mm. The five curves are representative of five compounds with normal boiling points at 80°, 110°, 210°, 260°, and 290°C. respectively. A size of chart which is satisfactory is 56 inches high and 38.75 inches wide with pressures from 0.1 mm. to 10^6mm. The values of T cover the range from −100°C. to +10,000°C., the 0° point being 17.25 inches from the left side or −100° point of the chart.

Some compounds, *e.g.*, the amyl alcohols, do not come within the family where they should belong. In general, aromatic compounds seem to lie in families on the Cox chart to a much greater degree than do aliphatic compounds.

COX CHART FAMILY	Infinite Point	
	°C.	10^6mm. Hg
(1) *Aliphatic hydrocarbons* The series C_nH_{2n+2}; also pinene, camphene, and limonene	1240	1.3
(2) *Aliphatic halides* Mono- and poly-halogen derivatives of the series C_nH_{2n+2} and C_nH_{2n}, except acetylene tetrachloride	1390	1.43
(3) *Aliphatic alcohols and ketones* The lower members of the alcohol series $C_nH_{2n+2}O$ and $C_nH_{2n}O$. The saturated ketones of the series $C_nH_{2n}O$; unsaturated ketones apparently are exceptions	610	1.5
(4) *Aliphatic acids and esters* The saturated acids of the series $C_nH_{2n}O_2$ where $n<7$, and the esters $C_nH_{2n}O_2$ where $n<6$	520	0.24
(5) *Aliphatic esters* The saturated esters of the series $C_nH_{2n}O_2$ where $n>5$; also acetoacetic ester; *iso*-butyl oxalate; benzyl, linalyl, bornyl, and menthyl acetates; bornyl propionate and *n*-butyrate; methyl, ethyl, *n*-propyl, and *iso*-butyl benzoates; methyl salicylate	1100	1.1
(6) *Aliphatic acids* The saturated acids of the series $C_nH_{2n}O_2$ where $n>6$ and the unsaturated acids of the series $C_nH_{2n-2}O_2$ from $n=4$ to $n=11$; also chloroacetic and benzoic acids	1100	4.2
(7) *Alkyl benzenes* The series C_nH_{2n-6}, C_nH_{2n-8}, and their ring halogen derivatives	1500	2.0
(8) *Phenols* The series $C_nH_{2n-6}O$ and *m*-chlorophenol	1900	9.0
(9) *Aromatic alcohols* The series $C_nH_{2n-6}O$ and their ring halogen derivatives	3300	20.0
(10) *Anilines* The series $C_nH_{2n-5}N$ and their ring halogen derivatives; also benzylamine	1300	2.3
(11) *Alkyl naphthalenes* The series C_nH_{2n-12} and their ring halogen derivatives	1320	1.0

FUSING POINTS AND COMPO-

Information furnished by The Standard Pyrometric Cone Co., Columbus, O.

The fusing point values given in the table below have only a relative or theoretical value, being a summarized outline of determinations made by the U. S. Bu. of Standards (*Jour. Am. Ceramic Soc.* 9, 70 (1926) and are approximate values given to the nearest 5°C from the average of many determinations; therefore, between any two cones there may be an error of ±5°C. The values apply only when the cones are heated in kilns where the gases are normally oxidizing and free from oxides of sulfur. If the cones show a hardening of the surface ("skin effect") because of exposure to kiln gases with lack of oxygen, small corrections must be made. Kilns rich in sulfur oxides because of the fuel employed or wares which give off sulfur dioxide may cause appreciable variation in fusing points. Fusion of a cone is said to have been attained when the tip touches the base upon which the cone has been set.

From what has been stated above it is evident that pyrometric cones are not intended as a means of measuring temperature. **Their sole purpose is to serve as a guide in the firing of ceramic wares.** Since both the cones and the wares are composed of ceramic materials they are similarly affected by variable conditions within the kiln, and are thus a more reliable guide for firing than any device which indicates only one of these variables, namely the temperature. When cones behave erratically, they indicate abnormal kiln conditions which in many instances affect the

Cone Number	Fusion Temperature When Heated: Slowly 20°C. per hr. °C.	Slowly 20°C. per hr. °F.	Rapidly 150°C. per hr. °C.	Rapidly 150°C. per hr. °F.	Color Scale	Heat Treatment Range

SITION OF PYROMETRIC CONES

ware unfavorably. Cones in series should go over seriatim otherwise something is wrong with the firing conditions. Although fusion temperatures of cones are affected by sulfur oxides and since the majority of ceramic wares are fired with sulfurous fuel (or the ware itself contains sulfides or sulfates), nevertheless it does not follow that cones are not satisfactory under these conditions. A factory selects by trial a cone which has a satisfactory end point for its ware and since all the cones used by it go through this sulfur treatment, so far as that factory is concerned all have practically the same relative end points.

Series Classification—The *Soft* or *Decorating* series begins with No. 022, softening at dull red heat and runs through to No. 011, the temperature range between numbers being approximately 30°C or 54°F. Of these, No. 017 represents the temperature usually employed for liquid bright gold, and most overglaze colors for pottery and glass are made to work best at this heat. These cones contain lead and are quite sensitive to reducing gases; they should be used only in muffle kilns or where they cannot come in contact with flames. The *Low* temperature series includes Nos. 010 to 01 and is used chiefly for firing red burning clay products and soft glazes. The *Intermediate* temperature series includes Nos. 1 to 20 and is used chiefly for firing buff and white clay products and hard glazes. The *High* temperature series includes Nos. 23 to 42 and is used chiefly for firing and testing refractory materials.

A SHORT GLOSSARY OF CERAMIC TERMS

Compiled by F. C. SMITH, B. S. (Chem. Eng.) and R. O. HUMMEL
of The Harshaw Chemical Co., Cleveland, Ohio.

Albany slip, a natural glaze burning brown to black.

Anneal, to relieve strains by heat.

Bait, a device for grabbing glass prior to drawing.

Belleek, a soft translucent ivory porcelain, usually very thin.

Bisque (body), unglazed, fired clayware.

Blunging, a mechanical mixing of clay or slip with water, and separating from sand and pebbles; washing.

Body stain, cf. *ceramic colors.*

Bone china, a china made with a body containing bone ash.

Casing, coating one piece of glass with another while hot.

Casting (pottery), forming pottery by pouring slip into a porous mold; e. g. in plaster of Paris.

Casting (glass), pouring glass from a crucible to a plate; flat glass.

Ceramic, clay or siliceous products hardened by the action of heat.

Ceramic colors—

Body stains, colors used in the body.

Engobe, colors used in a slip over a body or between the body and the glaze.

Glass colors, fusible colors fired over glassware.

Glaze stains, colors used in the glaze.

Lustres, organic solutions of metals which when applied to pottery and fired give iridescent metallic films.

Overglaze, fusible colors fired over glazed ware.

Underglaze, color applied over the body before glazing.

China, translucent vitrified glazed opaque ware, body usually vitrified before glazing.

Cloisonne (enamel), colored vitrified enamel on a metal base in which the different colors are separated by metal strips.

Cloisonne ware, colored pottery in which the different colored glazes are separated by a narrow line of hard black glaze.

Colors, cf. *ceramic colors.*

Cones, pyramid shaped fusible bodies of progressive softening order, employed as a guide in determining the finishing point of the ceramic kiln.

Continuous furnace or lehr, a furnace or lehr in which the firing takes place in a continuous operation.

Copper heads, copper colored spots in ground coat enamel.

Cords, variations in the density of glass.

Crackle (Craquelle), cracks in glaze due to crazing and which are sometimes produced intentionally.

Cranny, the sharp edge of a marver.

Crawl, a grouping of glaze, slip, or enamel during drying or firing, generally due to fineness of particles.

Crazing, the development of fine cracks caused by excessive contraction of a glaze or enamel.

Decalcomania, designs produced on enamels, pottery, or glass by transferring to them vitreous colors on paper and then firing.

Deflocculation, a dispersion of particles and agglomerates resulting in thinning the suspension; an excess of electrolytes; long; sol.

Devitrification, the crystallization of a vitreous material.

Dipping, an application of glaze or enamel by immersion and allowing the excess to drain off.

Draw, absorption of glaze by an unglazed surface nearby during firing.

Dunting, splitting of claywares due to silica inversion.

Egg shell, incomplete vitrification; cf. *devitrification.*

Enamel, a fusible vitreous coating for metals or claywares at low temperatures; an opaque coating.

Enamel frit, cf. *frit.*

Encaustic tile, a variety of tile having an inlaid design of a different color from that of the body of the tile; the term is now sometimes used to designate any dry pressed tile with a colored slip.

Engobe, cf. *ceramic colors.*

Faience, a general term covering "colored clay bodies glazed"; named after the town of Faenza, Italy.

Fining, removing small gas bubbles from molten glass; planing.

Firing racks, refractory racks or boxes for holding ware while firing.

Fishscaling, small fish-scale shaped chips jumping or chipping from enamel.

Flashing, coating a piece of glass with

A SHORT GLOSSARY OF CERAMIC TERMS

a thin layer of colored glass while hot.

Flocculation, the agglomeration of particles by the addition of electrolytes to give a proper consistency for dipping, casting, or spraying, setting-up; short; thickening.

Flux, a material or mixture having a low melting point; the first to fuse at a definite temperature.

Frit, any fused substance or mixture quenched; enamel frit; glaze frit.

Gathering, the collecting of glass on a blow-pipe.

Glass colors, cf. *ceramic colors.*

Glaze, vitrifiable coating for brick, bisque, porcelain, or pottery, or stoneware body.

Glaze frit, cf. *frit.*

Glaze stain, cf. *ceramic colors.*

Glory hole, a furnace for reheating glass.

Glost, a term applied to glazed ware.

Glost kiln, a kiln for firing glaze.

Graining, the application and firing of a net work of one colored enamel or glaze over another colored enamel or glaze to imitate a natural wood or marble finish.

Green ware, formed but unfired pottery.

Grog, crushed bisque fire-brick, saggers, crucibles, or calcined clay.

Hacking, a stacking of claywares without the aid of stilts or saggers.

Hairlines, the fine lines appearing in fired enamel.

Intermittent kiln or lehr, a furnace or lehr that is loaded, fired, allowed to cool and unloaded; intermittent charges.

Jacks, cf. *stilts.*

Jigger, a machine for shaping pottery by means of a rotating mold and a profile tool.

Jumpers, small chips of enamel that jump from finished surface.

Kiln, a furnace or oven for firing pottery.

Lehr, a furnace for annealing or decorating glass.

Lustres, cf. *ceramic colors.*

Majolica, a rather general term for a colored, enameled, clay body; named after the Island of Majorca.

Marver, a polished stone or steel plate for working glass while blowing.

Monkey pots, small crucibles for experimental glass melts.

Mosaic, the union of pieces of colored glass, stone, tile, etc. to form an artistic design, laid in metal, cement, etc.

Muffle furnace or kiln, a furnace or kiln so constructed that the space in which the ware is fired does not come in contact with fire or furnace gases.

Overglaze, cf. *ceramic colors.*

Parison, glass on the blow-pipe ready for final blowing.

Pin, cf. *stilts.*

Pin holes, holes left by the bursting of a blister during firing.

Planing, cf. *fining.*

Porcelain, a vitrified ware, generally translucent, made by one firing only.

Pot, a container for smelting.

Potters' wheel, a wheel for rotating plastic clay in forming ware by hand.

Pottery, a term commonly used to include all articles made of clay, or clay and mineral mixtures, and hardened by fire; in present usage the term does not include structural, refractory, or glass wares, or insulators.

Pugging, the intimate wet mixing of body constituents.

Punty, a tool upon which glass shapes are handled.

Pyrometric cone, cf. *cones.*

Refractory, having resistance to melting or fusion; a ware that does not fuse under 1500°C.

Saggers, refractory containers in which pottery is stacked for firing.

Seeds, the small bubbles in glass.

Seger cones, cf. *cones.*

Semi-vitreous china, semi-porous china.

Setters, a refractory support in which chinaware, tile, etc. are placed for firing. This ware is supported on its own base or its contour rests on sand, no stilts being used.

Setting-up, cf. *flocculation.*

Sherds (shords), broken saggers and bisque.

Shiners, shiny spots in enamel caused by fish-scaling or jumpers.

Shivering, a glaze or enamel expanding excessively on firing; chips.

Shords, cf. *sherds.*

Short, cf. *flocculation.*

Slip, a siliceous material (clay, glaze, engobe, or enamel) in aqueous suspension.

Slushing, the application of a heavy-bodied enamel or glaze by dipping and shaking off the excess.

Spalling, a disintegration on the sur-

A SHORT GLOSSARY OF CERAMIC TERMS

face of refractories, due to continued expansion and contraction, or to the formation of salts and the swelling of salts in service.

Spitout, a glaze defect conceded to be due to moisture in the body and which appears on refiring to the decorating temperature.

Spurs, cf. *stilts.*

Stilts, refractory pieces for supporting or separating ware in saggers during burning; various shapes are known as pins, jacks, spurs, or thimbles, etc.

Stones, refractory lumps in glass.

Tank, a furnace for smelting glass.

Tearing, cracks appearing in enamel during drying.

Terracotta, buff burned porous clay-ware used for interior and exterior decoration; sometimes glazed in colors.

Thickening, cf. flocculation.

Thimbles, cf. *stilts.*

Throwing, hand-forming pottery on a potter's wheel.

Tile, a fired clay body, white or colored, glazed or unglazed, porous or vitrified, in structural shapes; varieties are named according to method of manufacture and use; e.g. drain, encaustic, floor, hollow, mosaic, quarry, wall, etc.

Underglaze, cf. *ceramic colors.*

Watermark, discoloration of enameled or glazed ware after firing caused by an accumulation of soluble salts during drying.

COMMONLY USED CERAMIC MATERIALS
Composition, Formula, Trade Name, and Synonym

Compiled by F. C. SMITH, B. S. (Chem. Eng.) and R. O. HUMMEL
of the Harshaw Chemical Co., Cleveland, Ohio

See also the table *Common or Trade Names of Chemicals with Synonyms and Formulas,* and the tables on *Minerals.*

Material	Essential Composition	Formula
Adularia	Cf. potash feldspar	$K_2O \cdot Al_2O_3 \cdot 6SiO_2$
Albite	Cf. feldspar	$Na_2O \cdot Al_2O_3 \cdot 6SiO_2$
Andalusite	Aluminum silicate	$Al_2O_3 \cdot SiO_2$
Anorthite	Cf. lime feldspar	$CaO \cdot Al_2O_3 \cdot 2SiO_2$
Apatite	Tri-calcium phosphate	$(CaF)Ca_4(PO_4)_3 \pm Cl$
Aragonite	Cf. calcite	$CaCO_3$
Baddeleyite	Zirconium oxide	ZrO_2
Baryta	Barium oxide	BaO
Barytes (Barite)	Barium sulfate	$BaSO_4$
Bauxite	Hydrated aluminum oxide	$Al_2O_3 \cdot 2H_2C$
Beryl	Beryllium aluminum silicate	$3BeO \cdot Al_2O_3 \cdot 6SiO_2$
Biotite	Cf. magnesia mica	
Blanc-fixe	Barium sulfate	$BaSO_4$
Blue vitriol	Copper sulfate	$CuSO_4 \cdot 5H_2O$
Bone ash	Calcium phosphate and carbonate	$xCa_3(PO_4)_2 + yCaCO_3$
Borax	Sodium tetra-borate	$Na_2B_4O_7 \cdot 10H_2O$
Boric (Boracic) acid	Boric hydrate	$B_2O_3 \cdot 3H_2O$
Brown acid	Impure boric hydrate	$B_2O_3 \cdot 3H_2O$
Calcite	Calcium carbonate	$CaCO_3$
Calcothar	Calcined copperas	Fe_2O_3
Celestite	Strontium sulfate	$SrSO_4$
Chalk	Calcium carbonate	$CaCO_3$
Chile niter (nitre)	Sodium nitrate	$NaNO_3$
Chile saltpeter	Sodium nitrate	$NaNO_3$
China clay	Hydrated aluminum silicate	$Al_2O_3 \cdot 2SiO_2 \cdot 2H_2O$
Chromite	Ferrous chromite	$FeO \cdot Cr_2O_3$
Colemanite	Calcium borate	$2CaO \cdot 3B_2O_3 \cdot 5H_2O$
Copperas	Ferrous sulfate	$FeSO_4 \cdot 7H_2O$
Cornwall stone	Soda-potash aluminum silicate	Indefinite
Cristobalite	Silicon dioxide	SiO_2
Crocus martis	Ferric oxide	Fe_2O_3
Cryolite	Sodium aluminum fluoride	$3NaF \cdot AlF_3$
Cullet	Scrap glass	Indefinite
Cyanite (Kyanite)	Aluminum silicate	$Al_2O_3 \cdot SiO_2$
Diaspore	Hydrated aluminum oxide	$Al_2O_3 \cdot H_2O$

COMMONLY USED CERAMIC MATERIALS

Material	Essential Composition	Formula
Diatomaceous earth	Silicon dioxide	SiO_2
Diopside	Calcium magnesium silicate	$CaO \cdot MgO \cdot 2SiO_2$
Dolomite	Calcium magnesium carbonate	$CaCO_3 \cdot MgCO_3$
English chalk	Calcium carbonate	$CaCO_3$
Epsom salts	Magnesium sulfate	$MgSO_4 \cdot 7H_2O$
Feldspars	.....	.....
Albite (soda)	Sodium aluminum silicate	$Na_2O \cdot Al_2O_3 \cdot 6SiO_2$
Anorthite (lime)	Calcium aluminum silicate	$CaO \cdot Al_2O_3 \cdot 2SiO_2$
Orthoclase (potash)	Potassium aluminum silicate	$K_2O \cdot Al_2O_3 \cdot 6SiO_2$
Flints	.....	.....
Cristobalite	Silicon dioxide	SiO_2
Diatomaceous earth	Silicon dioxide	SiO_2
Ganister	Silicon dioxide	SiO_2
Kieselguhr	Silicon dioxide	SiO_2
Quartz	Silicon dioxide	SiO_2
Sand	Silicon dioxide	SiO_2
Silica	Silicon dioxide	SiO_2
Tridymite	Silicon dioxide	SiO_2
Tripoli	Silicon dioxide	SiO_2
Fluorite	Calcium fluoride	CaF_2
Fluorspar	Calcium fluoride	CaF_2
French chalk	Hydrated magnesium silicate	$3MgO \cdot 4SiO_2 \cdot H_2O$
Ganister	Silicon dioxide	SiO_2
Gibbsite	Hydrated aluminum oxide	$Al_2O_3 \cdot 3H_2O$
Granite	Mixture of feldspar, mica and quartz	Indefinite
Gypsum	Calcium sulfate	$CaSO_4 \cdot 2H_2O$
Heavy spar	Barium sulfate	$BaSO_4$
Hematite	Ferric oxide	Fe_2O_3
Ilmenite	Ferrous titanate	$FeO \cdot TiO_2$
Kaolin	Hydrated aluminum silicate*	$Al_2O_3 \cdot 2SiO_2 \cdot 2H_2O$
Kaolinite	Hydrated aluminum silicate**	$Al_2O_3 \cdot 2SiO_2 \cdot 2H_2O$
Kieselguhr	Silicon dioxide	SiO_2
Lepidolite	Lithia mica	Indefinite
Leucite	Hydrated potassium silicate	$K_2O \cdot Al_2O_3 \cdot 4SiO_2$
Lime (quick)	Calcium oxide	CaO
Lime stone	Calcium carbonate	$CaCO_3$
Limonite	Hydrated ferric oxide	$2Fe_2O_3 \cdot 3H_2O$
Litharge	Lead oxide	PbO
Magnesia	Magnesium oxide	MgO
Magnesite	Magnesium carbonate	$MgCO_3$
Magnetite	Ferrous-ferric oxide	Fe_3O_4
Marble	Calcium carbonate	$CaCO_3$
Marcasite	Iron sulfide	FeS_2
Marl	Mixture of calcium carbonate and lay	Indefinite
Mica	Mixed hydrated aluminum silicates	.....
(magnesia) (Biotite)	Magnesium aluminum silicate	$H_2K(Mg,Fe)_3(Al,Fe)(SiO_4)_3$
(potash) (Muscovite)	Potassium aluminum silicate	$H_2KAl_3(SiO_4)_3$
Minium (red lead)	Plumbus plumbate	Pb_3O_4
Monazite sand	Rare earth phosphates	Indefinite
Mullite	Aluminum silicate	$3Al_2O_3 \cdot 2SiO_2$
Muscovite (potash mica)	Potassium aluminum silicate	$H_2KAl_3(SiO_4)_3$
Niter (nitre)	Potassium nitrate	KNO_3
Niter (nitre) cake	Mixture of sodium sulfate and bisulfate	$x\,NaHSO_4 + y\,Na_2SO_4$
Ochre	Mixture of clay, ferric hydroxide and lime	Indefinite
Orthoclase (feldspar)	Potassium aluminum silicate	$K_2O \cdot Al_2O_3 \cdot 6SiO_2$
Paris white	Calcium carbonate	$CaCO_3$
Pearl ash	Potassium carbonate	K_2CO_3
Pegmatite (granite)	Mixture of feldspar, mica and quartz	Indefinite
Plaster of Paris	Calcium sulfate	$CaSO_4 \cdot \frac{1}{2}H_2O$
Powder blue	Cobalt silicate	Indefinite
Pyrite (pyrites)	Iron sulfide	FeS_2
Pyrolusite	Manganese dioxide	MnO_2
Quartz	Silicon dioxide	SiO_2
Quick lime	Calcium oxide	CaO
Red lead (minium)	Plumbus plumbate	Pb_3O_4
Rock salt	Sodium chloride	$NaCl$
Rouge	Ferric oxide	Fe_2O_3
Rutile	Titanium oxide	TiO_2

*Amorphous
**Crystalline

COMMONLY USED CERAMIC MATERIALS

Material	Essential Composition	Formula
Salt (Rock salt)	Sodium chloride	NaCl
Salt cake	Commercial sodium sulfate	Na_2SO_4
Salt peter (salt petre)	Potassium nitrate	KNO_3
Sand	Silicon dioxide	SiO_2
Siderite	Ferrous carbonate	$FeCO_3$
Sienna	Ferric aluminum silicate, clay and sand	Indefinite
Silica	Silicon dioxide	SiO_2
Sillimanite	Aluminum silicate	$Al_2O_3 \cdot SiO_2$
Smaltz (Smalts)	Cobalt silicate	Indefinite
Soapstone (talc)	Hydrated magnesium silicate	$3MgO \cdot 4SiO_2 \cdot H_2O$
Spanish oxide	Impure ferric oxide	Fe_2O_3
Steatite (talc)	Hydrated magnesium silicate	$3MgO \cdot 4SiO_2 \cdot H_2O$
Talc (French chalk, steatite, soapstone)	Hydrated magnesium silicate	$3MgO \cdot 4SiO_2 \cdot H_2O$
Terra alba (gypsum)	Calcium sulfate	$CaSO_4 \cdot 2H_2O$
Tincal (borax)	Sodium tetra-borate	$Na_2B_4O_7 \cdot 10H_2O$
Tripoli	Silicon dioxide	SiO_2
Trydimite	Silicon dioxide	SiO_2
Tuscany acid	Crude boric acid	$B_2O_3 \cdot 3H_2O$
Umber	Iron-manganese silicate and clay	Indefinite
White lead	Basic lead carbonate	$2PbCO_3 \cdot Pb(OH)_2$
Whiting	Calcium carbonate	$CaCO_3$
Willemite	Zinc silicate	$2ZnO \cdot SiO_2$
Witherite	Barium carbonate	$BaCO_3$
Wollastonite	Calcium silicate	$CaO \cdot SiO_2$
Zaffre (powder blue)	Cobalt silicate	Indefinite
Zircon	Zirconium silicate	$ZrO_2 \cdot SiO_2$
Zirconia	Zirconium oxide	ZrO_2

MELTING POINTS OF SOME COMPOUNDS IN COMMON USE IN CERAMICS

Compiled by F. C. SMITH, B. S. (Chem. Eng.) and R. O. HUMMEL
of The Harshaw Chemical Co., Cleveland, Ohio.

The compounds in the table below are arranged according to increasing melting points. The melting points are values selected from those reported in the *International Critical Tables* or in the *Jour. Amer. Ceramic Soc.* The values followed by an **E** are for eutectics.

Melting Point °C.	Formula
415 E	$77.6PbO, 6.1B_2O_3, 16.3SiO_2$
532 E	$88.0PbO, 12.0SiO_2$
570 E	$24.2Na_2O, 35.2B_2O_3, 40.6SiO_2$
650 E	$60.8PbO, 7.1Al_2O_3, 31.45SiO_2$
655 E	$23.7K_2O, 37.2B_2O_3, 39.1SiO_2$
746±10	$2PbO \cdot SiO_2$
750 E	$76.5BaO, 23.5B_2O_3$
766±10	$PbO \cdot SiO_2$
780 E	$55.0K_2O, 45.0SiO_2$
800 E	$50K_2O \cdot B_2O_3, 50Na_2O \cdot B_2O_3$
800 E	$17.5Na_2O, 5.4Al_2O_3, 77.1SiO_2$
830 E	$51.5Na_2O, 48.5SiO_2$
860 E	$18.4Na_2O, 81.6SiO_2$
870 E	$17.4K_2O, 5.2Al_2O_3, 77.4SiO_2$
874±2	$Na_2O \cdot 2SiO_2$
880E	$17.5K_2O, 82.5SiO_2$
888±10	PbO
948	$Li_2O \cdot SiO_2$
976	$K_2O \cdot SiO_2$

Melting Point °C.	Formula
980	$K_2O \cdot 2TiO_2$
995 E	$35CaO, 65B_2O_3$
1010	$2Li_2O \cdot SiO_2$
1041	$K_2O \cdot 2SiO_2$
1070 E	$47.5CaO, 52.5B_2O_3$
1088±2	$Na_2O \cdot SiO_2$
1100±10	$Na_2O \cdot Al_2O_3 \cdot 6SiO_2$
1157 E	84.3 albite, 15.7CaO
Cone 3 E	71.5 feldspar, 8.6$CaCO_3$, 7.7 kaolin, 12.2 flint

SILICON DIOXIDE INVERSION TABLE

Compiled from the values given in the *International Critical Tables*, published by McGraw-Hill Book Co., New York, and Mellor: *A Comprehensive Treatise on Inorganic and Theoretical Chemistry*, published by Longmans, Green and Co., New York.

Crystalline Variety	Inversion Temperature, °C.
αQuartz	Stable to 575
βQuartz	Stable to 870 ± 10
β_2 Tridymite	Stable to 1470 ± 10
βCristobalite	Melts at 1625-1710
αTridymite	Stable to 117

Crystalline Variety	Inversion Temperature, °C.
β_1 Tridymite	Stable to 163
β_2 Tridymite	Stable to 1470
βCristobalite	Melts at 1625
αCristobalite	Stable to 225
βCristobalite	Melts at 1625

COEFFICIENTS OF CUBICAL EXPANSION FOR VARIOUS SOLIDS

The table below gives the average value over the range from room temperature to the melting point expressed in millimeters per degree Centigrade, as determined by Winkelmann and Schott, and Mayer and Havas. See also Landrum, *Enamels* (1918), published by The Harshaw Chemical Co., Cleveland, Ohio. See also the table *Coefficients of Cubical Expansion for Liquids and Solutions.*

Substance	Coefficient
AlF_3	4.4×10^{-7}
Al_2O_3	5.0×10^{-7}
As_2O_5	2.0×10^{-7}
B_2O_3	0.1×10^{-7}
BaO	3.0×10^{-7}
BeO	4.7×10^{-7}
CaF_2	2.5×10^{-7}
CaO	5.0×10^{-7}
CeO_2	4.2×10^{-7}
CoO	4.4×10^{-7}
Cr_2O_3	5.1×10^{-7}
CuO	2.2×10^{-7}
Fe_2O_3	4.0×10^{-7}
K_2O	8.5×10^{-7}
LiO_2	2.0×10^{-7}
MgO	0.1×10^{-7}

Substance	Coefficient
MnO_2	2.2×10^{-7}
NaF	7.4×10^{-7}
Na_3AlF_6	7.4×10^{-7}
Na_2O	10.0×10^{-7}
*$NaSbO_3$	4.6×10^{-7}
NiO	4.0×10^{-7}
P_2O_5	2.0×10^{-7}
PbO	4.2×10^{-7}
Sb_2O_5	3.6×10^{-7}
SiO_2	0.8×10^{-7}

BALL MILL SPEEDS

For the mathematics of the ball mill, see E. W. Davis, *Am. Inst. Min. and Met. Eng.* Vol. 61 (1920), and Haultain and Dyer, *Canadian Inst. Min. and Met.*, June 1922.

Diameters being equal the efficient speed of a ball mill depends upon the size and amount of the pebbles or balls, slippage between the lining of the mill and the charge (consistency), and the size of the charge.

In general practice the ball mill is first half filled with balls or pebbles, and then half as much enamel or glaze is added, and the required water if it is to be wet ground.

The speeds in the table given below are an average covering a large variety of materials and conditions.

Inside Diameter of Ball Mill in Feet	Speed of Ball Mill in RPM*
8.0	12 to 14
7.5	16 to 18
6.0	17 to 20
5.0	20 to 23
4.5	22 to 24
4.0	23 to 27

Inside Diameter of Ball Mill in Feet	Speed of Ball Mill in RPM*
3.5	25 to 28
3.0	26 to 30
2.5	30 to 38
2.0	35 to 40
1.5	40 to 53
1.0	42 to 55
Laboratory mills	50 to 85

*For dry mills use the higher values.

FORMULAS FOR CALCULATING PHYSICAL PROPERTIES OF CERAMIC MATERIALS

Reprinted from 1928 *Standards Report Amer. Ceramic Society*, by permission.

1. DETERMINATION OF WATER IN CERAMIC MATERIALS

Dry a 200 gram sample to constant weight at 110-50°C.

$$\% H_2O = \frac{W - D}{W} \times 100$$

W = weight of material received
D = weight of material after drying to constant weight

2. DETERMINATION OF TOTAL LINEAR DRY AND FIRED SHRINKAGE

Green bar size 2½″×4½″×9″; gauge marks 8″ apart
Fire to 1400°C. in not less than 5 hrs.; natural cooling

$$\% \text{ Shrinkage} = \frac{Lw - Lb}{Lw} \times 100$$

Lw = length of specimen in plastic state
Lb = length of specimen after firing to 1400°C.

3. DETERMINATION OF WATER OF PLASTICITY

$$T = \frac{Wp - Wd}{Wd} \times 100$$

T = % water of plasticity
Wp = weight of plastic test piece
Wd = weight of dry test piece

4. DETERMINATION OF SHRINKAGE WATER

$$t_1 = \frac{Vp - Vd}{Wd} \times 100$$

t_1 = % shrinkage water

Vp = plastic volume in cc.
Vd = dry volume in cc.
Wd = dry weight in grams

5. DETERMINATION OF PORE WATER

$t_2 = T - t_1$
t_1 = % shrinkage water
t_2 = % pore water
T = % water of plasticity

6. DETERMINATION % VOLUME SHRINKAGE

$$b = \frac{Vp - Vd}{Vd} \times 100$$

b = % volume shrinkage
Vp = plastic volume
Vd = dry volume

7. DETERMINATION OF LINEAR SHRINKAGE

$$a = 100\left(\sqrt[3]{1 + \frac{b}{100}} - 1\right)$$

a = % linear shrinkage

FORMULAS FOR CALCULATING PHYSICAL PROPERTIES OF CERAMIC MATERIALS

8. DETERMINATION OF THE TRUE SPECIFIC GRAVITY

$$Gt = \frac{w-p}{(w-p)-(w_2-w_1)}$$

Gt = true specific gravity
w = weight of stoppered pycnometer and sample
p = weight of stoppered pycnometer
w_1 = weight of stoppered pycnometer filled with water
w_2 = weight of stoppered pycnometer sample and water

9. DETERMINATION OF APPARENT POROSITY

$$P = \frac{Sf-Wf}{Vf} \times 100$$

P = % apparent porosity
Sf = weight of saturated fired test piece in grams
Wf = weight of fired test piece in grams
Vf = volume of fired test piece in cc.

10. DETERMINATION OF VOLUME CHANGE

$$b_l = \frac{Vd-Vf}{Vd} \times 100$$

b_l = % volume change
Vd = volume of the dry test piece in cc.

11. DETERMINATION OF APPARENT SPECIFIC GRAVITY

$$G = \frac{Wf}{Vf-(Sf-Wf)}$$

G = apparent specific gravity

12. DETERMINATION OF BULK SPECIFIC GRAVITY

$$Gb = \frac{Wf}{Vf}$$

Gb = bulk specific gravity

13. DETERMINATION OF MODULUS OF RUPTURE

$$M = \frac{3PL}{2bd^2}$$

M = modulus of rupture in kg./sq. cm.
P = breaking load in kg. (read to nearest 0.1 kg.)
L = distance between knife edges in cm.
b = breadth of bar in cm.
d = depth of bar in cm.

14. DETERMINATION OF TRANSVERSE STRENGTH

$$M = \frac{8PL}{\pi d^3}$$

M = modulus of rupture
P = load in pounds at rupture
L = distance between supports
d = diameter of specimen in inches
$\pi = 3.1416$

SHRINKAGE CONVERSION TABLES

For a complete explanation of the following tables, the reader is referred to the original paper by WESTMAN, Jour. Am. Ceramic Soc. 11, No. 9, p. 715, (1928).

Copyright by A. E. R. Westman, reprinted by permission.

Relations Between Linear and Volume Change

Nature of change	Percentage basis	Volume change to linear change	Linear change to volume change	Percentage basis	Nature of change
Expansion	Initial values	$a = 100\left[\sqrt[3]{\frac{b}{100}+1}-1\right]$	$b = 100\left[\left(\frac{a}{100}+1\right)^3-1\right]$	Final values	Contraction (or shrinkage)
	Final values	$a = 100\left[\sqrt[3]{\frac{b}{100}-1}+1\right]$	$b = 100\left[\left(\frac{a}{100}-1\right)^3+1\right]$	Initial values	

Conversion of Percentage Basis

Nature of change in size	Equations* for converting: Percentage of initial value to final value	Percentage of final value to initial value
Expansion	$c = \frac{100d}{100+d}$	$d = \frac{100c}{100-c}$
Contraction	$c = \frac{100d}{100-d}$	$d = \frac{100c}{100+c}$

Calculation of Design Factors, Combination of Changes

Nature of changes	Percentage basis	Equation* for calculating resultant per cent change	Percentage basis	Nature of changes
Both expansions	Initial values	$Z = X + Y + \frac{XY}{100}$	Final values	Both contractions (or shrinkages)
	Final values	$Z = X + Y - \frac{XY}{100}$	Initial values	

*In the equations, a = % linear change, b = % volume change, c = % change based on final value, and d = % change based on initial value; substitutions are to be made arithmetically. Z = % resultant change or overall change, X = % change in first process (e.g. drying), and Y = % change in second process (e.g. firing); if X and Y are percentages of final values, Z will be a percentage of the final value.

SHRINKAGE CONVERSION TABLE
TABLE I

Four Figure Table for Converting:

(1) Volume Drying Shrinkage (per cent of plastic volume) to Linear Drying Shrinkage (per cent of plastic length),

(2) Volume Firing Shrinkage (per cent of unfired or dry volume) to Linear Firing Shrinkage (per cent of unfired or dry length), and

(3) Volume Expansion (per cent of final volume) to Linear Expansion (per cent of final length).

Per cent volume change	Per cent volume change 0.0	0.1	0.2	0.3	0.4	0.5	0.6	0.7	0.8	0.9	Differences

SHRINKAGE CONVERSION TABLE
TABLE II

Four Figure Table for Converting:

(1) Volume Drying Shrinkage (per cent of dry volume) to Linear Drying Shrinkage (per cent of dry length),

(2) Volume Firing Shrinkage (per cent of fired volume) to Linear Firing Shrinkage (per cent of fired length), and

(3) Volume Expansion (per cent of initial volume) to Linear Expansion (per cent of initial length).

Per cent volume change	Per cent volume change										Differences
	0.0	0.1	0.2	0.3	0.4	0.5	0.6	0.7	0.8	0.9

SIEVES AND SCREENS

The following terms are often employed in reporting the results of a screen analysis.

Cumulative Per Cent is the term employed to express the percentage of the total amount of a material which would remain on a testing sieve if only one sieve were used for testing the entire sample; to obtain the **cumulative weight,** it is necessary to add the weight of all of the material which remains on sieves coarser than the one in question to the amount remaining on the sieve in question. When such data is plotted as a curve, each point on the curve represents the *total* material that would be retained if only the one sieve represented by that particular point were used in the sieve analysis.

Effective Size is a term customarily employed in specifications for filtration sands; effective size is measured by that opening in millimeters which will just pass 10% of a representative sample of sand.

Uniformity Co-efficient is the numerical value obtained by dividing the sieve opening (in millimeters) which will pass 60% of the sample by the sieve opening (in millimeters) which will just pass 10% of the sample.

CERAMIC EQUIVALENT WEIGHTS

Based Upon the International Atomic Weights of 1933.
Compiled by F. C. SMITH, B. S. (Chem. Eng.) and R. O. HUMMEL of The Harshaw Chemical Co., Cleveland, Ohio.

Abbreviations used in the table:

anhyd., anhydrous
atm., atmosphere of pressure
d., decomposition
diss., dissociation
$-H_2O$, loss of 1 mole water
monocl., monoclinic
m. p., melting point
$-O$, loss of 1 atom of oxygen
RO, base equivalent
R_2O_3, amphoteric equivalent
RO_2, acid equivalent
subl., sublimes
<, below or less than
>, above or greater than

Mineral or Compound	Formula	Formula Weight	Equivalent Weight			Melting Point °C.
			RO	R_2O_3	RO_2	
Albite (soda feldspar)	$Na_2O \cdot Al_2O_3 \cdot 6SiO_2$	524.29	524.29	524.29	87.38	1100±
Alum (ammonium)	$Al_2(SO_4)_3 \cdot (NH_4)_2SO_4 \cdot 24H_2O$	906.63	.....	906.63	.....	94
Alum (potash)	$Al_2(SO_4)_3 \cdot K_2SO_4 \cdot 24H_2O$	948.75	948.75	948.75	.....	92
Alum (soda)	$Al_2(SO_4)_3 \cdot Na_2SO_4 \cdot 24H_2O$	916.55	916.55	916.55	.....	61

**Position of this oxide depends upon acid-base ratio; status questionable.

INDEX OF REFRACTION

The index of refraction of air, 1.000294, is so near unity that it is commonly used as a more convenient standard than vacuum. After measurement of the index of a substance in any medium, as air, its index in a vacuum may be computed, being equal to the index as obtained by measurement multiplied by the index (measured in a vacuum) of the medium used.

Index of refraction varies inversely with the wave length of light employed, being greater for violet than for red light. This variation is known as *dispersion* and is greater (in general) for liquids than for solids. The yellow light of sodium (*D*) is commonly employed as an approximate mean value for all parts of white light. Other wave lengths which have been used in determinations of refractive index are those corresponding to certain spectrum lines of some of the elements and are indicated by the symbols of the elements or by the letters *A'*, *C*, *D*, *E*, *F*, *G'*, and *H* which are the Fraunhofer designations. The wave lengths most commonly employed are:

Ca = (*H*)	= 3968Å	= 396.8$m\mu$	= 0.3968 × 10^{-4}cm.
Hγ = (*G'*)	= 4340Å	= 434.0$m\mu$	= 0.4340 × 10^{-4}cm.
Hβ = (*F*)	= 4861Å	= 486.1$m\mu$	= 0.4861 × 10^{-4}cm.
Tl = ...	= 5350Å	= 535.0$m\mu$	= 0.5350 × 10^{-4}cm.
Hg = ...	= 5791Å	= 579.1$m\mu$	= 0.5791 × 10^{-4}cm.
He = (*E*)	= 5876Å	= 587.6$m\mu$	= 0.5876 × 10^{-4}cm.
Na = (*D*)	= 5893Å	= 589.3$m\mu$	= 0.5893 × 10^{-4}cm.
Hα = (*C*)	= 6563Å	= 656.3$m\mu$	= 0.6563 × 10^{-4}cm.
Li = (*Red*)	= 6708Å	= 670.8$m\mu$	= 0.6708 × 10^{-4}cm.
A = ...	= 7594Å	= 759.4$m\mu$	= 0.7594 × 10^{-4}cm.
Kα = (*A'*)	= 7699Å	= 769.9$m\mu$	= 0.7699 × 10^{-4}cm.

The index of refraction is lowered by raising the temperature. This thermal variation of index is considerable in many liquids and negligible (affecting only the 4th or 5th decimal place) in crystals. Pressure plays a noticeable role only with gases.

Optically all substances may be classified as follows:

- Isotropic Group
  - Liquids
  - Isometric system solids
- Anisotropic Group
  - Uniaxial
    - Tetragonal — Positive or Negative
    - Hexagonal — Positive or Negative
  - Biaxial
    - Orthorhombic — Positive or Negative
    - Monoclinic — Positive or Negative
    - Triclinic — Positive or Negative

ISOTROPIC GROUP (SOLIDS*)

Isotropic substances transmit light with equal velocity in all directions (isoaxial) and include gas, liquid, amorphous materials such as resins and glasses, and isometric crystals. In the table below most of the substances are isometric; a considerable number are amorphous and therefore rather variable and indefinite in their chemical composition and all their properties; a few, which are included also in their proper birefracting group, are birefracting, but their birefringence is so weak or uncertain as to make them easily mistaken for isotropic substances.

Arrangement. The substances are arranged in the order of increasing values of refractive index.

INDEX OF REFRACTION

ANISOTROPIC GROUP—UNIAXIAL

Uniaxial crystals have two refractive indices, one of the rays vibrating parallel to the optic axis and another at right angles to this direction. The ordinary ray is indicated by the symbol ω and the extraordinary ray by the symbol ϵ. If $\epsilon > \omega$ in a uniaxial substance, the substance is optically positive; if the reverse is true, negative. Uniaxial crystals may be considered simply as a small group of biaxials in which β is equal to α for a positive crystal, and to γ for a negative one.

The greater part of the substances of this group are tetragonal or hexagonal, but some that are strictly biaxial but with nearly zero axial angle are included here as well as in their proper biaxial group. A considerable proportion of these biaxial substances with nearly uniaxial optical properties have also nearly hexagonal form.

Arrangement. The substances are listed in the order of increasing values of the ω index.

Abbreviations. Hex., hexagonal; Tetr., tetragonal; Trig., trigonal; Rhomb., rhombohedral.

INDEX OF REFRACTION

ANISOTROPIC GROUP—BIAXIAL

Biaxial crystals have three refractive indices, two lying in one plane and the third in another plane of the particle. These indices are indicated by α, β, γ for the least, intermediate and the greatest index respectively of the substance. If $\gamma-\beta>\beta-\alpha$ the crystal is optically positive; if the reverse is true, negative. The indices α, β, γ have directions of vibration X, Y, Z respectively.

The greater part of the substances of this group are chiefly orthorhombic, monoclinic or triclinic.

Arrangement. The substances are listed in the order of increasing values of the β index.

Abbreviations. Ax. pl., axial plane; *a*, front and rear crystal axis; *b*, right and left crystal axis; *c*, vertical crystal axis; Lg., large; Mon., monoclinic; Mod., moderate; Ortho., orthorhombic; *r*, red light; $r>v$ (or $r<v$) signifies that the optic axial angle in red light is greater than (or less than) the optic axial angle in violet light; Sm., small; Tric., triclinic; $2V$, the true axial angle between the optic axes; X, Y, and Z, the vibration directions of the fastest, the intermediate, and the slowest ray respectively; $\wedge$, angle, for example $Z \wedge c$ is the angle between Z and c; 100, 010, 110, etc., the Miller symbols of crystal faces and forms; $=$, to indicate parallel, for example $X=a$ signifies X parallel to a; $\perp$, perpendicular. In monoclinic crystals the extinction angle is commonly measured from the vertical axis c to X, Y, or Z; if this angle lies in the obtuse angle β it is considered positive (+), but if this angle is in the acute angle β between a and c, it is negative (−).

INDEX OF REFRACTION (LIQUIDS)

Arrangement. The substances are arranged in the order of increasing values of refractive index (n_D) to facilitate use of the table as a means of identification of pure liquids. No substance is listed more than once. To ascertain if a desired compound is listed in the table and to find its position in the table reference must be made to the formula index at the end of the table. When possible, values were selected at or near 20°C. In using the table for identification of an unknown pure liquid, consideration must be given to the effect of temperature. The index of refraction of a liquid decreases with rise in temperature and this thermal variation differs with various substances but is approximately 0.0004 per 1°C.

Specific Gravity. As an aid in applying formulas for calculation of refractive index (*q. v.*) the specific gravity is given at the same temperature as used in the refractive index determination.

Beil. Ref. In the column so headed will be found the reference to the volume and page numbers of the 4th edition of Beilstein: *Handbuch der Organischen Chemie.* Where the Roman numeral, which indicates the volume number, is preceded by an asterisk, reference is to the first supplementary volumes.

It is to be noted that the symbols α, β, γ which are often employed in reporting refractive index of liquids, refer to the wave length of light used and signify the wave length corresponding to the Hα, Hβ and Hγ spectrum lines. In the case of refractive index of biaxial crystals the symbols α, β and γ have a different significance (*q. v.*).

References. The information in the table has been collected mainly from the following sources:

Beilstein: *Handbuch der Organischen Chemie*, 4th edition. Published by Springer, Berlin.

FORMULA INDEX

For finding compounds listed in the table: *INDEX OF REFRACTION (LIQUIDS).*

The system used in this formula index is essentially the same as that employed in *Richter's Lexikon der Kohlenstoff Verbindungen.* The succession of the elements combined with carbon is as follows: H, O, N, S, F, Cl, Br, I. All the other elements are placed in alphabetical order. The arrangement depends (1) on the number of carbon atoms, (2) on the number of the other elements which, in addition to carbon, are contained in the compounds, (3) on the kind of elements, which in addition to carbon are contained in the molecule, in accordance with the order as stated above, and (4) on the number of atoms of each element which, in addition to carbon, is contained in the compound. Thus 2 III means two carbon atoms combined with three other elements; *e. g.*, $C_2H_2O_2F_2$ 13, is a compound with 2 carbon atoms and *3* other elements, and it is the 13th compound in the table to which this formula index is a part.

REFRACTIVE INDEX OF AQUEOUS ALCOHOL SOLUTIONS

The table below gives the readings of the Zeiss Immersion Refractomer for various concentrations of ethyl alcohol in water. The values were calculated by B. H. St. John from the data of Doroshevskii and Dvorzhanchik. Reprinted by permission from the Official and Tentative Methods of Analysis, 3d Edition (1930), published by The Association of Official Agricultural Chemists at Washington, D. C.

CONVERSION OF SCALE DIVISIONS OF THE IMMERSION REFRACTOMETER TO REFRACTIVE INDEX

Originally the immersion instrument was designed with a single prism (A) of crown glass which allowed only the range from n_D 1.32 to 1.36 to be covered. By a choice of glass and prism angle it has been found possible with a battery of six prisms to extend the upper limit of the range to 1.54. Each prism of the series overlaps the one immediately above so that there is no lost region from 1.32 to 1.54. The ranges covered by these prisms are: A–1.32539 to 1.36674; B–1.36428 to 1.40608; C–1.39860 to 1.43830; D–1.43620 to 1.47562; E–1.47320 to 1.51335; F–1.50969 to 1.54409. Prism A is the standard to which the values in the table below apply. For the other prisms (B to F) the index of refraction is not standardized as between different manufacturers nor for different lots issued by the same manufacturer. For these prisms (B to F) it is necessary to use the table supplied with any particular instrument and impossible to publish any conversion tables which would be universally applicable.

Example: Scale division 25.1 on prism A corresponds to the refractive index $n_D = 1.33705 + 0.000038 = 1.33709$.

Scale Division	n_D	Scale Division	n_D	Scale Division	n_D

INDEX OF REFRACTION CALCULATIONS

For Organic Liquids.

Reference: Smiles, *The Relation between Chemical Constitution and some Physical Properties* (1910). Published by Longmans, Green and Co., London.

In the Lorentz and Lorenz formula:

$$\frac{n^2-1}{n^2+2}\times\frac{1}{d}=k$$

n is the index of refraction of a liquid at a given temperature, d is the density of the substance at the same temperature, and k, which is nearly independent of the temperature, is a constant known as the *specific refraction*. The product $M\times k$, where M is the molecular weight of the substance, is the *molecular refraction;* this quantity (Mk) is additive and can be calculated for most organic liquid compounds from empirically deduced atomic and structural refractive constants. Such refractive constants (k) for sodium (D) light are given in the following table:

	k		k
C	2.418	N	12.45; 23.21; 32.65; 43.59; 53.00; 64.36; 72.48; 82.47; 93.05; 103.79; 113.93; 122.65; 132.27; 142.71; 153.776; 163.901; 174.10; 183.46
H	1.100		
O	(*a*) 1.525; (*b*) 2.211; (*c*) 1.643; (*d*) 1.64		
S	(*e*) 7.69; (*f*) 7.97; (*g*) 7.91; (*h*) 8.11	NO_2	197.59; 207.44; 216.72; 227.30; 237.51
Hal.	(*i*) 5.967; (*j*) 8.865; (*k*) 13.900		
Str.	(*m*) 1.733; (*n*) 2.398; (*p*) 0.71; (*r*) 0.48	NO	245.91; 255.37

In the form of: (a) (OH); (b) C:O; (c) ether OR; (d) ester OR; (e) SH; (f) RSR; (g) RCNS; (h) RSSR; (i) Cl; (j) Br; (k) I; (m) double bond; (n) triple bond; (p) 3-membd. ring; (r) 4-membd. ring; (1) aliph. prim. amine; (2) arom. prim. amine; (3) aliph. sec. amine; (4) arom. sec. amine; (5) aliph. tert. amine; (6) arom. tert. amine; (7) hydroxylamine; (8) hydrazine; (9) aliph. cyanide; (10) arom. cyanide; (11) aliph. oxime; (12) prim. amide; (13) sec. amide; (14) tert. amide; (15) imidine; (16) oximido; (17) carbimido; (18) hydrazone; (19) alkyl nitrate; (20) alkyl nitrite; (21) nitro paraffin; (22) nitro arom.; (23) nitramine; (24) nitrite; (25) nitrosoamine.

Example: Allylacetic acid ($CH_2:CH\cdot CH_2\cdot CH_2\cdot CO\cdot OH$) has the following observed constants: $n_D^{7.5}=1.4341$; $d_4^{7.5}=0.9903$; molecular weight = 100.064. From this the calculated value of Mk is found as follows:

5 C	12.090
8 H	8.800
1 O′	1.525
1 O″	2.211
1 =	1.733
Mk_D	26.359

The observed value of Mk as calculated from the Lorentz and Lorenz formula is:

$$100.064\times\frac{(1.4341)^2-1}{(1.4341)^2+2}\times\frac{1}{0.9903}=26.319$$

Optical exaltation is characteristic of substances containing conjugated double bonds (single bonds alternating with double bonds); *i.e.*, their molecular refractions (Mk) are usually one or more units in excess of the calculated values.

For Minerals.

Reference: Larsen and Berman, *The Microscopic Determination of the Nonopaque Minerals*, 2d edition (1934); U. S. Geological Survey, Bull. 848. Washington, D. C.

In the Gladstone and Dale formula:

$$\frac{n-1}{d}=K,\ and\ K=k_1\frac{p_1}{100}+k_2\frac{p_2}{100}+etc.,$$

n is the mean index of refraction, d is the density, K is the specific refractive energy, k_1, k_2, etc. are the specific refractive energies of the components, and p_1, p_2, etc.

the weight percentages of the components of a mineral. The mean index of refraction is $\frac{2\omega+\epsilon}{3}$ or $\frac{\alpha+\beta+\gamma}{3}$ unless the substance is highly birefringent when the mean index is better expressed by $\sqrt[3]{\omega^2\epsilon}$ or $\sqrt[3]{\alpha\beta\gamma}$. The specific refractive energies of the chief constituents of minerals are given in the following table:

	Molecular weight	k		Molecular weight	k

[a] Water and ice.
[b] Average.
[c] Alums, etc.
[d] Calculated from compounds containing the oxide.
[e] Calculated from the oxide.
[f] Calculated from feldspar, feldspathoids, etc.
[g] Isometric oxide.
[h] Monoclinic oxide.
[i] Orthorhombic oxide.
[k] Calculated from native sulfur.
[m] Calculated from sulfides; values vary.

Example: Sodium tetraborate, $Na_2B_4O_7\cdot5H_2O$, has the following observed constants: formula, $Na_2O\cdot2B_2O_3\cdot5H_2O$; molecular weight, 292; contains, 21.2% Na_2O; 48% B_2O_3; 30.8% H_2O; d, 1.815; $\omega=1.461$; $\epsilon=1.474$. From the table k for Na_2O, 0.181; k for B_2O_3, 0.220; k for H_2O, 0.340. Therefore, $K=0.181\times21.2\%+0.220\times48\%+0.340\times30.8\%=0.24869$. Substituting in the Gladstone Dale formula:

$$\frac{n-1}{1.815}=0.24869, \text{ or } n=1.4514 \text{ by calculation.}$$

$$\text{The observed average value of } n=\frac{2\omega+\epsilon}{3}=\frac{2(1.461)+1.474}{3}=1.465$$

Crystal Type	Crystal Units	Type of Binding	Characteristic Properties: Optical
Ionic	Simple and complex ions	Electrical attraction between ions of opposite signs	Transparent; color if present is due to ions
Silicate	O^{--} or F^{-} ions; Si^{4+} or Be^{2+} or Al^{3+} and other positive ions	Weak to moderate polarization	Refractivity due to positive ions
Homopolar	Atoms of the fourth group and of groups equidistant on either side of it	Homopolar bonds throughout or strongly polarized ionic bindings	Transparent with high refractivity or opaque metalloidal
Molecular	Inert gas atoms. Non-polar and polar molecules	Van der Waal's forces or residual electric fields	Transparent. Optical properites due to molecules
Layer	Strongly polarizing and easily polarized ions	In layers, homopolar or polarized ionic. Between layers, molecular	As homopolar
Metallic	Positive ions and electron gas	Electrical attraction between positive ions and electron gas	Opaque (due to free electrons)
Metalloidal	Metal atoms and atoms of the sulfur and arsenic groups	Mixture of homopolar, ionic, and metallic binding	Opaque, metallic or transparent with high refractivity and color

OF CRYSTALS

Freshmen," by C. W. Stillwell; *Jour. Chem. Education*, 10, 598 (1933).

Characteristic Properties			
Electrical	Thermal	Mechanical	Typical Crystals
Moderate insulators; in high fields conduct by transfer of ions	Fairly high melting point; ionization occurs in liquid, vapor	Strength increasing with higher ionization and decrease in distance beweeen ions. Fracture by cleavage	NaCl, CaF_2 $CaCO_3$, K_2SO_4, $(NH_4)_2PtCl_6$
When polarization is slight, dissolve in ionizing solvents (water); when stronger, are insoluble	Very high melting points, glasses formed on cooling of melt	Very hard with tendency to cleave or fracture conchoidally	Olivine, Mg_2SiO_2; Cyanite, Al_2SiO_5; Garnet, $R^{II}_3R^{III}_2$, Si_3O_{12}; Spinel, Al_2MgO_4, Al_2O_3, SiO_2
Diamond is a perfect insulator. The others conduct metalloidally. Very insoluble	Very high melting points with tendency to vaporize except in more metalloidal	Very hard. Hardness less for metalloidal types	Diamond, Zinc Blende, ZnS; Wurtzite, ZnS; Carborundum, CSi. Many intermediate compounds— γ brass
Insulators except when very polar; soluble in non-ionizing (molecular) solvents	Melting point very low with neutral atoms	Very soft, hardness increasing with polarity of molecules	Argon, A; CO_2; Ice, H_2O; Paraffins, C_nH_{2n+2}; Cellulose
Various, similar to both molecular and homopolar	Various, similar to both molecular and homopolar	Cleaving readily in layers which are soft and flexible	Graphite, C; CdI_2
Conductors, conductivity inversely proportional to number of free electrons	Moderate to very high melting points. Long liquid interval	Moderate hardness increased by alloying	Copper, iron, sodium, zinc
Medium to bad conductors. Soluble only with decomposition	Tendency to vaporize or decompose at high temperatures	Moderately hard to soft. Properties a mixture of those of other types	NiAs, FeS, FeS_2

LATTICE CONSTANTS OF STANDARD CRYSTALS

Values selected from Siegbahn, *Spektroskopie der Rontgenstrahlen*, 2d. Ed., Julius Springer, Berlin, 1931.

Crystal	Lattice Constant in cm. $\times 10^{-11}$ at 18°C.		
	First order	Second order	Third order
Calcite	3029.04	3029.34	3029.40
Gypsum	7579.07	7583.29	7584.15
Mica	9927.58	9938.93	9941.04
Quartz	4244.92	4245.74	4245.90
Rock salt	2814.00	.....	.....

TOTAL MASS ABSORPTION VALUES FROM FORMULA

The values given in the following table make it possible to calculate the mass absorption for any wave length in the given range by substituting in the formula in column 3. The values are those of Richtmyer.

Absorption material	Wave length, λ, in Å	Total mass absorption μ/ρ
Al	0.1 to 0.4	$14.45\lambda^3+0.15$
Al	0.4 to 0.7	$14.30\lambda^3+0.16$
Fe	0.1 to 0.3	$110\lambda^3+0.18$

FLUORESCENCE AND PHOSPHORESCENCE

Ultraviolet radiation causes many substances to emit light; if the emission occurs only when the ultraviolet radiation is present the phenomenon is known as *fluorescence*. If the emission occurs after removal of the ultraviolet radiation the afterglow is termed *phosphorescence*. Fundamentally both fluorescence and phosphorescence are identical.

Exciting agents need not be ultraviolet light. Fluorescence can be due to: heat (*thermoluminescence*); visible light (*photoluminescence*); X-rays; electrical waves; γ rays; radio waves; cathode rays (*cathodoluminescence*); β rays; α rays; molecular beams; neutron and deuteron beams; positrons; streams of various ions (*ionoluminescence*); friction (*triboluminescence*); crystallization (*crystalloluminescence*); cold; pressure; mechanical excitation; sound waves (*sonoluminescence*); oxidation and special chemical reactions (*bio-* and *chemi-luminescence*); flames; electrolysis; and several others. For additional data the references which follow should be consulted.

Fluorescence is characteristic of numerous substances, but in many it is highly variable, depending on the nature, purity, history, and condition of the material. Fluorescence generally occurs best in solution. Actually, only a few very pure and dry substances fluoresce since most substances have impurities which activate luminescence. Water and crystalline condition also predominate as activators. A *phosphor* is a luminescent system consisting of a base and a trace of impurity called an activator: $AB+M$ where A may be Ba, Ca, Na, K, Mg, Li, etc., associated with anion B which may be sulfide, oxide, tungstate, silicate, carbonate, etc. M is the trace of metal which may be U, Mn, Cu, rare earths, etc. A flux may be incorporated with this, and very complex phosphors are built upon this basis. The notation *ZnCuS* represents a typical phosphor-Cu activated ZnS.

The exciting agent used in most studies is usually one of two types of ultraviolet radiation suitably filtered to eliminate visible light. One wavelength is most suited to the study of organic substances and is called *long wavelength radiation*, the tentative standard being Hg = 3650Å. *Short wavelength radiation* is usually best suited for excitation of inorganic substances and its tentative standard wavelength is Hg = 2537Å (*resonance radiation*).

References which have been consulted for data in the following tables include:

Dake and De Ment: *Fluorescent Light and Its Applications*, Chemical Publishing Company, New York (1941); Dake and De Ment: *Ultraviolet Light and Its Applications*, Chemical Publishing Company, New York (1942); De Ment and Dake: *Uranium and Atomic Power*, Chemical Publishing Company, New York (1941); De Ment: *Fluorescent Chemicals and Their Applications*, Chemical Publishing Company, New York (1942); Radley and Grant; *Fluorescence Analysis in Ultraviolet Light*, D. Van Nostrand Company, 3d edition, New York (1939).

The arrangement in the following tables is alphabetical with abbreviations for filtered ultraviolet light being L = long λ = 3650Å, and S = short λ = 2537Å. The symbol LS is used to indicate both long and short wavelengths. The variability of fluorescent response should always be considered when using these tables. Aqueous solutions are indicated by the abbreviation *soln.*

FLUORESCENT CHEMICALS

In the following table, fluorescence most representative of the substance is listed together with the wavelength which evokes it. As with other substances fluorescence of chemicals may be widely variant, differing with the purity, history, structure, and state of the compound. Solution and alteration in pH markedly affect the fluorescence of many chemicals. However, numerous closely related compounds can easily be discriminated by their fluorescence. Impurities in inorganic substances usually enhance fluorescence but in many organic substances fluorescence is a property of the molecule. Fluorescence is a valuable adjunct in the study of materials and further information can be obtained from the references quoted. Several chemicals which emit ultraviolet light when excited by X-rays are also included in the table.

Name	λ	Fluorescence	Name	λ	Fluorescence

Hydrocinnamic aldehyde	L	Weak green	Manganese iodide	S	Yellowish
Hydrofuramide	L	Bright pink	Manganese stearate	L	Bright deep rose
Hydroxylammonium sulfate	S	Light blue	Manganese oxalate	L	Pale whitish
8-Hydroxyquinoline	L	Strong dark purple	Mannitol glyceryl monolaurate	L	Deep green-brown
Hydroquinone	L	Violet	Mannitol glyceryl monoleate	L	Brownish-blue
Indium cyanide	L	Weak blue-green	Mannitol glyceryl monostearate	L	Blue-gray
Indium *o*-iodoxy-benzoate	L	Light lavender	Mannitol triricinoleate	L	Deep green
Indium molybdate	L	Pale red-brown	Mercurous chloride	L	Bright pinkish
Indium salicylate	L	Bright blue-green	Mercury salicylate	L	Strong lavender
Indium tungstate	L	Grayish	Mercury salicylamide	L	Bluish
Indole	L	Violet-blue	Methanol	L	Very slight bluish
Inositol	L	Lavender	Methyl acetophenone	L	Gray-brown
Iron(ic) 8-hydroxy-quinolinate	L	Deep blue-black	Methylamine	L	Slight bluish
Iron(ous) 8-hydroxy-quinolinate	L	Blue-brown	Methyl anthranilate	L	Blue-green
Isoquinine	L	Violet	Methyl cinnamate	L	Bright violet
Lactose	L	Lavender	*β*-Methyl esculin	L	Brilliant blue
Lanthanum 8-hydroxy-quinolinate	L	Pale yellow-green	Methyl formate	L	Greenish
Lanthanum molybdate	L	Whitish	Methyl lactate	L	Greenish
Lanthanum salicylate	L	Bright light blue	2-Methyl-1,4-naphthoquinone	L	Lavender-white
Lanthanum silicate	S	Whitish	Methylglycolphene-tidin	L	Violet
Lanthanum tungstate	S	Whitish	2-Methyl-2,4-pentanediol	L	Light blue
Lead acetate	S	Medium blue	Methyl salicylate	L	Green
Lead bromide	S	Yellowish	*β*-Methylumbelli-ferone, soln.	L	Brilliant medium blue
Lead carbonate	S	Yellowish	Morphine	L	Pale green to lavender
Lead chloride	S	Whitish-yellow	Musk ambrette	L	Yellowish-brown
Lead iodide	S	Scarlet	Musk ketone	L	Yellowish-brown
Lead sebacate	L	Lavender-white	Musk xylol	L	Yellowish-brown
Lead monostearate	L	Vivid blue	Narceine	L	Violet-blue
Lead sulfate	S	Yellowish	Narcotine	L	Violet
Lead naphthenate	L	Brilliant blue-green	Nembutal	L	Bluish-violet
Legumin	L	Bright light blue	Neodymium chromate	L	Light yellow
Leptandrin	L	Red-violet	Neodymium cyanide	L	Blue
Linalyl acetate	L	Yellow-green	Neodymium ferrocyanide	L	Deep coral
Lithium benzoate	L	Whitish-violet	Neodymium molybdate	S	Coral
Lithium oxalate	L	Lavender	Neodymium nitrate	L	Pinkish-white
Lithium salicylate	L	Bright blue-green	Neodymium tellurite	L	Rose-blue
Lycopodium	L	Strong pinkish	Neodymium thiosulfate	L	Rose
Magnesium ammonium arsenate	L	Whitish	Neodymium salicylate	L	Vivid blue-green
Magnesium oxide	L	Scarlet to reddish	Nerolin	L	Violet
Magnesium 8-hydroxyquinolinate	L	Brilliant golden	Nickelous 8-hydroxy-quinolinate	L	Strong brownish
Magnesium phosphate	L	Blue			
Magnesium salicylate	L	Purple-green			
Magnesium stearate	L	Blue-white			
Magnesium sulfate	L	Usually blue-white			
Manganese acetate	S	Reddish			
Manganese bromide	S	Whitish

Theobromine	L	Brilliant blue-green	Yttrium salicylate	L	Bright medium blue
Theobromine calcium salicylate	L	Bright blue	Yttrium silicate	S	Deep blue
Thiochrome	L	Bright bluish	Yttrium tungstate	S	Bluish
Theophyllin ethylene-diamine	L	Bright blue-green	Zinc carbonate	S	Light lavender
Thorium 8-hydroxy-quinolinate	L	Deep green	Zinc hydroxide	S	Blue-violet
Titanium dioxide	L	Strong violet-white	Zinc 8-hydroxy-quinolinate	L	Brilliant green
Titanium stearate	L	Gray-blue-tan	Zinc oxalate	S	Green (if impure)
Tocopherol	L	Bright blue-green	Zinc oxide	S	Yellow-green
Tributyl citrate	L	Weak blue-green	Zinc palmitate	L	Blue-white
Tributyl phosphate	L	Weak blue	Zinc potassium cyanide	S	Lavender
Triethyl phosphate	L	Slight bluish	Zinc sebacate	L	Whitish
Trimethylamine	L	Slight bluish	Zinc stearate	L	Blue
Tris(hydroxymethyl)-aminomethane	L	Deep pink	Zinc sulfanilate	L	Purple-blue
Tris(hydroxymethyl)-nitromethane	L	Greenish-blue	Zirconium nitrate	S	Pale bluish
Uranin, soln.	L	Brilliant yellow	Zirconium nucleate	L	Blue
Uranyl compounds	LS	Generally vivid yellow-green	Zirconium oxide	S	Whitish
			Zirconium tungstate	S	Gray-blue
			Zirconium uranyl nitrate	S	Yellowish

† Emits ultraviolet rays under influence of X-rays.

FLUORESCENT MINERALS AND GEMS

Many mineral species luminesce, but the response often varies according to the locality, history, and exciting agent. A wide variety of fluorescent colors may be noted in the same species, although in a few the response is consistent for all specimens. This also holds for phosphorescence, denoted in the following table by *P*. Therefore, close rules cannot be drawn about luminescence in most minerals.

Name	λ	Fluorescence	Name	λ	Fluorescence
Agate	LS	Variable; green when U containing	Hackmanite	....	Variable; strong orange(S), sometimes pinkish(L), P
Albite	S	Sometimes P			
Alexandrite	S	Feeble reddish	Halite	S	Vivid red, P
Alumnite	L	White	Hanksite	S	P
Alunite	S	Usually whitish	Hexagonite	LS	Reddish

FLUORESCENT MINERALS AND GEMS

Name	λ	Fluorescence	Name	λ	Fluorescence
Amythest	S	Infrequently feeble brownish	Hiddenite	S	Lilac
			Hydromagnesite	L	Medium green
Anglesite	S	Yellowish	Hydrozincite	S	Vivid blue, sometimes green or yellowish
Anorthoclase	S	Blue			
Apatite	S	Variable; blue to whitish	Ianthinite	....	Rarely fluorescent
Apophyllite	S	Yellowish	Johannite	LS	Strong yellow-green
Aragonite	....	Variable; green(S), red(S), P	Kunzite	S	Red or yellow, red-yellow, P
Autunite	LS	Bright yellow-green	Leucite	L	Orange
Axinite	S	Medium red	Metatorbernite	LS	Brilliant yellow-blue
Barite	L	Sometimes whitish P	Meyerhofferite	S	P
Barylite	S	Blue	Nasonite	S	Blue
Benitoite	LS	Strong medium blue	Opal	LS	Variable; sometimes greenish or yellow, perhaps P
Beryl	S	Usually only very feeble			
Borax	L	Greenish			
Calcite	....	Highly variable; bright red(S), sometimes bright green(S), P	Ozocerite	L	Bluish
			Pearl	LS	Variable; white, blue, or yellowish
Calcium-larsenite	S	Vivid yellow	Pectolite	S	Yellow, P
Celestite	S	Whitish P	Petroleum	LS	Bright blue
Cerusite	....	Variable; blue(S), yellow (L)	Powellite	S	Strong yellowish-white
			Priceite	S	Sometimes yellow
Chalcedony	....	Variable; greenish(S)	Pyromorphite	L	Usually white
Chalcocite	S	Bright yellow-green	Quartz	....	Highly variable; brownish(S), green(S), yellow(LS), sometimes P
Chrysoberyl	S	Usually only feeble			
Clinohedrite	S	Brilliant orange			
Colemanite	L	Variable; greenish	Ruby	LS	Variable; usually vivid red
Cuproscheelite	S	Bright yellow-white			
Curtisite	LS	Yellow-green	Sapphire	S	Variable; orange-red to red-blue
Dakeite	S	Bright yellowish-green			
Diamond	LS	Highly variable; blue, green, red, orange, yellow, P	Scheelite	S	Characteristic bright blue
			Selenite	S	Pale yellow, P
Dolomite	LS	Whitish to blue, P	Smithsonite	L	Usually greenish
Elaterite	L	Brownish	Sodalite	L	Orange-red
Epsomite	L	Pale bluish	Sphalerite	LS	Strong orange
Fluorapatite	S	Orangish	Spinel	S	Strong red
Fluorite	LS	Variable; blue, green, P	Strontianite	S	White
Glauberite	....	Sometimes P	Sulfur	L	Yellowish
Gummite	LS	Variable; dull purple	Torbernite	LS	Bright yellow-green
Gypsum	L	Usually greenish	Trona	L	Blue
Gyrolite	LS	Whitish	Uranocircite	S	Bright yellow-green
Uraniferous hyalite	LS	Yellow-green	β-Uranotil	LS	Medium yellow-green
			Vesuvianite	L	Yellow
Uranophane	S	Yellow-green	Wavellite	L	Green
Uranopilite	S	Strong yellow-green	Wernerite	LS	Vivid yellow
β-Uranopilite	LS	Brilliant yellow-green	Willemite	S	Brilliant green
Uranospathite	S	Bright yellow-green	Witherite	L	Yellowish
Uranospinite	S	Bright yellow-green	Wollastonite	S	Yellow-orange, P
Uranothallite	LS	Bright green	Zippeite	LS	Strong yellow-green
Uranotil	S	Medium yellow	Zircon	LS	Variable; pale orange

QUALITATIVE SPECTROGRAPHIC ANALYSIS TABLE

In the following table a selected list of the useful elements is given together with their interferences. In using this table, if no line is to be found at the wavelengths given as ***sensitive lines of an element,*** that element can be reported as 0.0%, 0.00%, 0.000%, or 0.0000%, the sensitivity varying with the line chosen, the element, and the mode of excitation. Where a line is to be found at the wavelength given for a ***sensitive line of an element,*** that element can be reported as present if it can be shown that no minor line from other elements in the sample is so close to the sensitive line that it cannot be differentiated from it with the instruments available.

All values in the table are taken from Harrison's *M. I. T. Wavelength Tables,* permission to do so having been granted by Professor George R. Harrison and by the Technology Press. The 1939 Edition, published by John Wiley and Sons, Inc., New York, was used.

The ***abbreviations*** used in the following table are those employed in the *M. I. T. Tables,* and are as follows:

bh, band head
d, double line
h, hazy, diffuse
l, shaded, or displaced to longer wavelengths
r, narrow self-reversal
R, wide self-reversal
s, shaded, or displaced to shorter wavelengths
w, wide or complex
W, very wide or complex
I, line classified as being emitted by the un-ionized atom
II, line classified as being emitted by the singly ionized atom
ʔ, line listed in M. I. T. Tables, but not found on a plate made from pure sample of the element in question*

The arrangement of the tables is as follows: The elements to be included are in bold face type and are in alphabetical order of their names. Under each element are listed the sensitive lines for which the interferences are given. These and other wavelengths are in Angstrom units. These sensitive lines, together with their interferences are then listed in order of decreasing wavelength. Each line is followed by its chemical symbol and arc intensity. In this intensity scale the most intense lines are given ratings of 9000, while the faintest lines recorded are assigned the value of 1. Lines of intermediate strength are given twenty-five different values in an effort to approximate their true relationship. To facilitate identification, the sensitive line is given in bold face type.

The interfering range is as follows:

Range in Å	Å above and below	Ditto for int. of 100 or more
10,000 to 4,000	1.5	2.5
4,000 to 3,000	1.0	2.0
3,000 to 2,000	0.5	1.0

Because of the fact that their lines do not appear in the arc spectra, all interfering lines due to the eighth group of inert gases, the seventh group of halogens, and to nitrogen, oxygen, and hydrogen have been omitted from the table. Most of the rare earths and other rare elements have also been omitted. The following elements were completely omitted: A, Ac, Br, Cl, Dy, Er, Eu, F, Gd, H, He, Hf, Ho, I, Il, Kr, La, Lu, Ma, N, Nd, Ne, O, Os, Pa, Pd, Po, Pr, Ra, Re, Rn, Ru, Sm, Tb, Tm, Xe, Yb.

All the interfering lines listed in the *M. I. T. Tables'* arc column and due to the following elements are given: Ag, Al, As, Au, B, Ba, Be, Bi, Ca, Cd, Cu, K, Li, Mg, Na, Pb, Sb, Si, Sn, Sr, and Zn. All interfering lines having an intensity of 10 or more in the arc are listed for all the elements. However, if lines under 10 are to be found in the *M. I. T. Tables* within the interfering range, the element symbol is given in parentheses at the end of the tabulation of interferences. For example, since ***Ni I*** is listed after the interferences for ***LEAD, 4057.82,*** this line is not to be used for the detection of lead in nickel. If, however, only small amounts of nickel are present, then line 4057.82 can be used.

See also the following table: ***Sensitive Lines of the Elements.***

SENSITIVE LINES OF THE ELEMENTS

In the following table the sensitive lines of the elements are arranged in order of decreasing wavelengths. The **abbreviations** are the same as those used in the preceding table, ***Qualitative Spectrographic Analysis Tables,*** which see. In addition, in the column headed ***Sensitivity*** the most sensitive line of the neutral or un-ionized atom is indicated by U1, and other lines by U2, U3, etc. in order of decreasing sensitivity. For the singly ionized atom, the corresponding designations are V1, V2, V3, etc. In cases where U1 is not given, the most sensitive lines lie outside the range of 10,000 to 2,000 Å.

This table is taken by permission of George R. Harrison and The Technology Press. The 1939 Edition, Published by John Wiley and Sons, Inc., New York, was used.

SINGLE ELECTRODE POTENTIALS AT 25°C

According to the convention used in this table, a positive (or negative) E_o means that the solution is *positive* (or *negative*) with respect to the electrode, as compared with a "normal" hydrogen electrode.

E_o is the single potential of the electrode, when the concentration of ions involved is one molar ("unity activity"). To calculate the single electrode potential E, if the ion concentration is other than one molar, the following equation is used:

$E = E_o - \frac{0.05915}{n} \log_{10} \frac{(C_p)^a}{(C_r)^b}$; where n = number of electrons (e) involved in the electrode reaction, C_p = ionic concentration of the products, C_r = ionic concentration of the reactants, a and b are the coefficients of products and reactants, respectively, in the electrode reaction. Solid, liquid and gaseous states are abbreviated s, l, and g respectively.

Examples

(1) If $[Cl^-] = 0.1$ M, in the Ag, AgCl, Cl^- electrode then:-

$$E = -0.2221 - \frac{0.05915}{1} \log_{10} \frac{1}{0.1} = -0.2813$$

(2) If $[Cr^{++}] = 0.2$ M and $[Cr^{+++}] = 0.5$ M, then:-

$$E = 0.400 - \frac{0.05915}{1} \log_{10} \frac{0.5}{0.2} = +0.376$$

(3) If $[Fe^{++}] = 0.1$ M, then $E = 0.441 - \frac{0.05915}{2} \log_{10} 0.1 = +0.471$

Of two electrodes, the one higher in the table (E_1) forms the negative pole of the cell, while the other electrode (E_2) forms the positive pole. The EMF of such a cell equals $E_1 - E_2$.

Example

For the cell: $\overset{(-)}{\underset{E_1 = 0.7618}{Zn,\ Zn^{++}(1\ M)}} \Big\| \underset{E_2 = -0.3441}{Cu^{++}\ (1\ M),\ Cu^{(+)}}$,

the EMF of this cell is $E_1 - E_2 = +0.7618 - (-0.3441) = 1.1059$ volts.

1. Modification of the single fluid Poggendorf cell by introduction of a porous pot separating anolyte from catholyte. In one type the carbon was inside the porous pot, the zinc outside; in another, the electrode positions were reversed.
2. $ZnSO_4$ and NaCl have been used in the anolyte and various concentrations of HNO_3 in the catholyte.

ELECTROMETRIC DETERMINATION OF HYDROGEN ION CONCENTRATION

For any single electrode, the equation

$$E = E_o - 2.303\frac{RT}{nF}log_{10}\frac{(C_p)^a}{(C_r)^b} \qquad (1)$$

is valid. See section on "Single Electrode Potentials at 25°C." **E** is the electrode potential in the case under consideration, E_o the single electrode potential when the concentration of *ions* involved is hypothetically one molar ("unit activity"). **R**, the "gas constant," has the value 1.9869 cal_{15} deg^{-1} $mole^{-1}$; **F**, the Faraday, is equivalent to 23074 cal_{15} $volt^{-1}$ $equiv^{-1}$; **T**, the absolute temperature; **n** is the number of electrons taking part in the electrode reaction; (C_p) the ionic concentration of the products and (C_r) of the reactants, respectively, in the electrode reaction, written so that the electrons appear on the *right* side of the equation. For the hydrogen electrode, the reaction is: $\frac{1}{2}H_2 = H^+ + e$, *a* is unity and there are no ionic reactants. $\frac{2.303\ R}{nF}$ has the value 0.000198322, and the single electrode equation may be simplified to

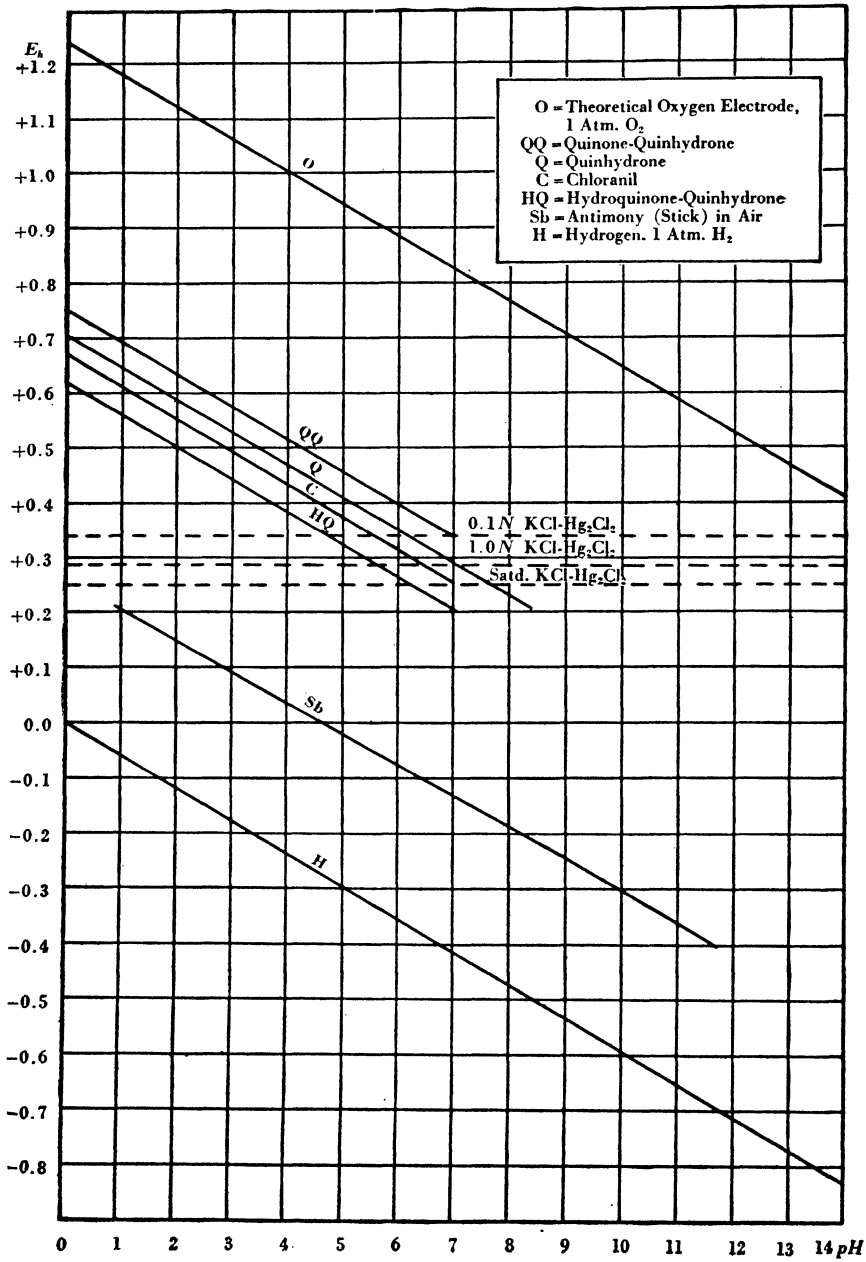
$$E_H = -0.000198322\ T\ log_{10}\ (H^+) \qquad (2)$$

The expression $-\log_{10}(H^+)$ is generally indicated by the symbol **pH**, the so-called "hydrogen-ion exponent," from the relation

$$pH = (H^+)^{-pH} = -log(H^+) = log\frac{1}{(H^+)}\ *$$

E_o, the single electrode potential of a hydrogen electrode in a solution normal with respect to hydrogen-ion concentration ("unit activity"), is taken as zero at all temperatures, and is the arbitrary standard to which all other single electrode potentials are referred. Then,

$$pH = \frac{E_H}{0.000198322\ T} \qquad (2a)$$



It is not possible to measure a single electrode potential except by comparison with another taken as a standard and opposed to the first in a cell or "gas chain," so that metallic contacts with the potentiometric circuit can be established. Within the cell, electrical contact must be made by reproducible means with minimum E. M. F. at the junction. The requirements are usually fulfilled in practice by one of the calomel electrodes, containing Hg, excess Hg_2Cl_2 and KCl solution at some definite concentration and saturated with Hg_2Cl_2. The potential difference between Hg and solution is then dependent upon Hg^+ concentration, in turn upon Cl^- concentration. Saturated KCl solution is used for the internal contact, since liquid junction potential will be minimized by the practically equal migration velocities of K^+ and Cl^-. Equations for calculating E_c, the single potential value of a calomel electrode at a given temperature, are shown in Table I.

*Note that a pH value is a negative logarithm, not merely a negative characteristic with mantissa positive, as taken from a table. See section on logarithms for method of changing sign of mantissa. The characteristic is negative because the log is of a number less than unity. Quite rarely is the pH scale applied to acid solutions with (H^+) greater than unity, but expressions like pH -0.2 referring to this case are sometimes used. It is customary to invert the signs. Hydrogen-ion concentration may be expressed as a common or decimal fraction of unit activity, or exponentially, as well as by pH. Thus,

$$(H^+) = 1/80000 = 0.0000125 = 1.25 \times 10^{-5} = \text{pH } 4.90$$

As only two decimal places are practically important, the last is evidently the handiest and most compact expression.

RELATION OF POTENTIAL, E_h, OF VARIOUS ELECTRODES TO *pH*

ELECTROMETRIC DETERMINATION OF HYDROGEN ION CONCENTRATION

Table I

Characteristics of Calomel Electrodes

Electrode	Common name	Equation for Ec at t°C. (volt)
Hg | Hg_2Cl_2 (s), 0.1 *N* KCl | satd. KCl | (a, b, c)	0.1 *N* calomel	+0.3380 −0.00006 (t −18)

765	.0000	+.0001	+.0001	+.0002	+.0003	+.0005	+.0007	+.0009
760	+.0001	+.0002	+.0002	+.0003	+.0004	+.0006	+.0008	+.0010
755	+.0002	+.0002	+.0003	+.0004	+.0005	+.0007	+.0009	+.0011
750	+.0003	+.0003	+.0004	+.0005	+.0006	+.0007	+.0010	+.0012
745	+.0003	+.0004	+.0005	+.0006	+.0007	+.0008	+.0010	+.0013
740	+.0004	+.0005	+.0006	+.0006	+.0008	+.0009	+.0011	+.0014
735	+.0005	+.0006	+.0006	+.0007	+.0009	+.0010	+.0012	+.0015

In a typical cell such as:

$$^{(-)}Pt,\ H_2\ (g,\ 760mm)\ |\ (H^+)\ |\ satd.\ KCl\ |\ 0.1\ N\ KCl,\ Hg_2Cl_2\ (s)\ |\ Hg^{(+)}$$
$$\qquad\qquad d \qquad\quad c \qquad\quad b \qquad\qquad a$$

the sum of the potentials at *a*, *b*, and *c* is given by E_c in Table I above, while the potential at *d* is the value E_H in equation (2a). With respect to zero potential represented by the hydrogen electrode in a solution of unit activity, potentials in solutions

less than normal will always be negative, and those of all calomel electrodes positive. But the potentiometer measures difference in potential in positive units, therefore $E = E_H + E_c$ and $E_H = E - E_c$. Hence,

$$pH = \frac{E - E_c}{0.000198322\ T} = -log_{10}(H^+) \qquad (2b)$$

Equation 2b may be used as long as the *partial pressure* of the hydrogen gas (barometer reading minus the vapor pressure of the solution at that temperature) is 760 mm. The effect of reduction in hydrogen pressure is to reduce the negative potential of the hydrogen electrode, thus shifting the indicated pH to the acid side. Therefore, a correction E_B, must be added algebraically to $E - E_c$, and the complete equation becomes

$$pH = \frac{E + E_B - E_c}{0.000198322\ T} \qquad (3)$$

The representative values for E_B in Table II were obtained as follows: Suppose the corrected barometer reading is 760 mm. and the temperature 25°C., at which the vapor pressure of water is 23.8 mm. The partial pressure of H_2 is then $760 - 23.8 = 736.2$ mm. Setting this equal to x in the formula

$$E_B = \frac{0.000198322\ T}{2} log_{10} \frac{760}{x}$$

the value 0.00041 volt is obtained on solving for E_B. Values from the table may be plotted and others read from the graph, but under most conditions the correction is negligible.

Table III

Values for 0.000198322 T at Various Temperatures

t°C.	Value	t°C.	Value	t°C.	Value	t°C.	Value
0	0.054162	17	0.057533	23	0.058723	29	0.059913
5	0.055153	18	0.057732	24	0.058921	30	0.060111
10	0.056145	19	0.057930	25	0.059120	35	0.061103
14	0.056938	20	0.058128	26	0.059318	38	0.061698
15	0.057137	21	0.058327	27	0.059516	50	0.064078
16	0.057335	22	0.058525	28	0.059715	70	0.068044

Example for the calculation of pH.—The potential of the cell

$(^-)Pt, H_2(g) \mid H^+ (pH = x) \mid$ satd. KCl $\mid$ 0.1 *N* KCl, $Hg_2Cl_2(s) \mid Hg(^+)$

is observed to be 0.6138 volt at 20°C and 765 mm. corrected barometer reading. From Table II, E_B is taken to be 0.0002 volt. From Table I, E_c is taken as 0.3379 volt. From Table III, 0.000198322T is taken as 0.05813. Substituting these values in (3), we have

$$pH = \frac{0.6138 + 0.0002 - 0.3379}{0.05813} = 4.75$$

Equations for Practical Work

The following equations, in which the barometric corrections are neglected, are satisfactory for most practical work.

(a) Hydrogen electrode with 0.1 *N* calomel electrode:

at 20°C, $pH = \frac{E - 0.3379}{0.0581}$; at 25°C, $pH = \frac{E - 0.3376}{0.0591}$

(b) Hydrogen electrode with saturated calomel electrode:

at 20°C, $pH = \frac{E - 0.2491}{0.0581}$; at 25°C, $pH = \frac{E - 0.2458}{0.0591}$

ELECTROMETRIC DETERMINATION OF HYDROGEN ION CONCENTRATION

Notes on Hydrogen Electrode

Directions for preparing the hydrogen electrode may be found in Clark's "*The Determination of Hydrogen Ions*," 3d edition, 1928, Williams and Wilkins Co., publishers, Baltimore, Md.

The hydrogen electrode cannot be used in the presence of salts of heavy metals, nor easily reduced substances in general. Thus, unsaturated organic acids, some alkaloids, etc., are reduced by hydrogen in the presence of the finely divided noble metal electrode which acts as a catalyst for the reduction. The electrode is very sensitive to traces of oxygen, so that highly purified hydrogen must be used in generous amounts. The commercial compressed hydrogen, however, is generally sufficiently pure for practical work. The hydrogen electrode is always negative with respect to all calomel electrodes, and the cell must be connected to the potentiometer with the former attached to the (−) binding post and the latter to the (+).

ELECTROMETRIC DETERMINATION OF HYDROGEN ION CONCENTRATION

Measurement of pH with the Quinhydrone Electrode

A bright platinum or gold electrode is usually employed. No hydrogen is required. The solution is saturated with quinhydrone, which is an equimolecular mixture of quinone and hydroquinone. The single electrode reaction is:

$$C_6H_4(OH)_2 \rightarrow C_6H_4O_2 + 2H^+ + 2e$$

Accordingly, the electrode equation is

$$E_H = E_{oq} - \frac{RT}{2F} \ln \frac{(C_6H_4O_2)(H^+)^2}{(C_6H_4(OH)_2)} \quad \text{or}$$

$$E_H = E_{oq} - \frac{RT}{2F} \ln \frac{(C_6H_4O_2)}{(C_6H_4(OH)_2)} - 2.303\frac{RT}{F} log_{10}\ (H^+)$$

Since quinone and hydroquinone are present in equimolecular proportions, it is assumed that their "activities" are equal in the solution. The second term on the right hand side of the equation therefore becomes zero, and

$$E_H = E_{oq} - 0.000198322\,T \log_{10}(H^+) \qquad (4)$$

This is the same as equation (2), with the constant term E_{oq}, which has a value $0.7177 - 0.00074t°C$ from 0° to 38°C. The quinhydrone single electrode must be paired with another, usually the satd. calomel electrode, to make a cell. It is *positive* to the calomel electrode over the greater part of the pH range in which it is applicable, but with a satd. calomel electrode at 25°C E is zero at pH 7.67. For measurements at higher pH values, the quinhydrone electrode must be connected to the (−) binding post of the potentiometer, and E considered negative in calculating pH.

Table V

Standard Electrode Potential, E_{oq}, for the Quinhydrone Electrode

$E_{oq} = 0.7177 - 0.00074t°C$									
t°C.	E_{oq}	t°C.	E_{oq}	t°C.	E_{oq}	t°C.	E_{oq}	t°C.	E_{oq}
15	0.7066	19	0.7036	23	0.7007	27	0.6977	35	0.6918
16	.7059	20	.7029	24	.6999	28	0.6970	38	.6896
17	.7051	21	.7022	25	.6992	29	0.6952	40	.6881
18	.7044	22	.7014	26	.6985	30	0.6955		

The general formula for calculation of pH value from the potential of a quinhydrone electrode is

$$pH = \frac{E_{oq} - E_e - E}{0.000198322\,T} \qquad (5)$$

The value of E, the potential read from the potentiometer, is considered positive if the metal of the quinhydrone electrode is connected to the (+) binding post of the potentiometer, negative if connected to the (−) binding post.
For instance, in the cell

$^{(+)}Pt|H^+$(quinhydrone) | satd. KCl | satd. KCl, $Hg_2Cl_2(s)$ | $Hg^{(-)}$

the platinum electrode is connected to the positive binding post, and the observed potential is 0.0200 volt at 20°. The value of E_{oq} at 20°C is read from Table V, E_e from Table I and 0.000198322 T from Table III. E is positive in this case and substituting

$$pH = \frac{0.7029 - 0.2496 - 0.0200}{0.05813} = 7.45$$

ELECTROMETRIC DETERMINATION OF HYDROGEN ION CONCENTRATION

To illustrate a second example, a case in which the quinhydrone electrode must be connected to the negative binding post of the potentiometer when the observed potential is 0.0100 volt at 20°C. E is considered negative and therefore must be added, when

$$pH = \frac{0.7029 - 0.2496 - (-0.0100)}{0.05813} = 7.97$$

Notes on the Quinhydrone Electrode

An electrode having an area of at least one square centimeter is desirable. If the platinum is sealed in glass with mercury for a connection, the seal is quite certain to crack sooner or later and the electrode then becomes unreliable. Platinum electrodes should be clean and free from stains, but need not be highly polished. Methods of cleaning platinum electrodes include (1) heating in fresh cleaning solution (sulfuric acid and potassium dichromate mixture), washing well with water and drying in air for twenty minutes; (2) boiling in nitric acid, then in 5 to 10% sodium acid sulfite, rinsing well with water and using at once. With a platinum electrode treated by method (2), very little quinhydrone is necessary, four drops of a saturated solution in acetone being sufficient for 50 milliliters of solution, for correct potentials in two minutes. Commercial quinhydrone is usually satisfactory. It should not be exposed to light or heated, as it decomposes with loss of quinone. The quinhydrone electrode cannot be used in the presence of active reducing or oxidizing agents, and it is also subject to protein and salt errors. Above pH 8.5 it becomes unreliable, both because hydroquinone has acid properties (K'_a is approximately 10^{-10}), and because it is appreciably oxidized by air in alkaline solutions.

Measurement of pH with the Glass Electrode

If a membrane permeable only to water, H, and OH ions, separates two solutions differing in pH, it can be shown from theory that there should be a difference in potential between the two solutions, in accordance with the equation

$$E = \frac{RT}{F} \ln \frac{(H)_1}{(H)_2}$$

A very thin film of certain kinds of glass, which may be considered a solid solution containing some water, appears to function as a membrane of limited permeability as indicated. The resistance of even the thinnest glass film is extremely high, therefore a quadrant electrometer or electron-tube amplifier must be used as the null instrument in the potentiometric circuit, to measure the potential of the chain:

$$\mathrm{Hg}\left|\mathrm{Hg_2Cl_2},\ \mathrm{KCl\ satd.}\right|\mathrm{KCl\ satd.}\left|\begin{matrix}\text{Sample}\\ \text{pH} = \text{x}\end{matrix}\right|\text{glass}\left|\begin{matrix}\text{Buffer}\\ \text{pH} = \text{c}\end{matrix}\right|\mathrm{KCl\ satd.}\left|\mathrm{KCl\ satd.,\ Hg_2Cl_2}\right|\mathrm{Hg}$$

The characteristics of glass films differ, so that each must be standardized by the use of buffers. Once the glass film has reached stability and the constants have been established, potential is found to vary with pH almost as predicted from theory. In practice, glass electrodes have been found satisfactory in sensitivity and speed in reaching equilibrium, and to remain stable for considerable lengths of time. It is possible to operate with very small volumes of sample solution, and the glass electrode appears to function solely as a pH indicator, without complication from oxidation-reduction potentials shown by metal electrodes. (Cf. Britton, "*Hydrogen Ions*," 2d edition, D. Van Nostrand Co., publishers, New York, 1932.)

Standard Solutions for Testing Electrodes

Potassium Acid Phthalate, 0.05 *M*.—The pH is accepted as 3.97 at all temperatures between 0° and 40°C. A 0.2 *M* solution is prepared from 10.209 grams of the pure salt dissolved and diluted to 250 ml. A portion may be diluted with three volumes of water for use. The 0.05 *M* solution deteriorates and is worthless in a few days, but the more concentrated solution is quite permanent.

"Standard Acetate." The pH value varies slightly with temperature having a value of 4.62 at 18°C, 4.63 at 25°C and 4.64 at 38°C. The solution contains

N acetic acid	50 ml.
N sodium hydroxide	25 ml.
Water to make	250 ml.

The sodium hydroxide must be pure and free from carbonate, and exactly twice the equivalent of acetic acid is added. Unless sealed and sterilized, molds will grow and consume the acid.

General Data

The following data apply to Tables VI, VII and VIII which pertain to systems involving a glass electrode. Since these three tables apply to various combinations of different glass electrodes and saturated calomel electrodes, the following data should be carefully read before using the tables to be sure that the correct table is used and also to apply the corrections (when needed and desired) for asymmetry or for errors caused by the presence of sodium, lithium or potassium salts in the solution being measured.

When using Tables VI, VII and VIII, the measured E.M.F. should be considered positive when the reference electrode (saturated calomel electrode) is connected to the positive terminal of the measuring instrument and should be considered negative when the reference electrode is connected to the negative terminal.

Table VI

Table VI should be used when making measurements with the L & N Cat. 7685 Glass Electrode and the L & N Cat. 7724 Saturated Calomel Electrode.

It is to be noted, however, that the first two pages of this Table are also for use when making measurements with a quinhydrone electrode and a saturated calomel electrode.

Table VII

Table VII should be used when making measurements with the following combinations of electrodes:

L & N Glass Electrode		L & N Reference Electrode (Saturated Calomel Electrode)
Std. 1199–10	and	Std. 119–11 or Cat. 7724
Std. 1199–12	and	Std. 1199–13

It is to be noted that zero volts in this Table occurs at 4 pH.

ELECTROMETRIC DETERMINATION OF HYDROGEN ION CONCENTRATION

Table VIII

Table VIII should be used when making measurements with the following combinations of electrodes:

L & N Glass Electrodes		L & N Reference Electrodes (Saturated Calomel Electrode)
Std. 1199–8	and	Std. 1199–11 or Cat. 7724
Std. 1199–14	and	Std. 1199–13

It is to be noted that zero volts in this Table occurs at 7 pH.

Asymmetry Correction—To determine the asymmetry correction for a given electrode system (glass electrode with a saturated calomel electrode), proceed as follows:

(1) Place the electrode system in a buffer solution of known pH value and measure the pH of the buffer solution with the electrode system. If the measuring instrument being used reads E.M.F., convert this E.M.F. value to pH by referring to the voltage table which applies to the glass electrode being used.

(2) The difference between the measured pH value of the buffer solution and the known value of this solution represents the asymmetry correction to be applied.

Under ordinary conditions the asymmetry changes very little. However, if the glass electrode is heated to 70° C. or higher, quite an appreciable change may occur.

Sodium, Lithium and Potassium Errors—Sodium, lithium and potassium salts in solution will cause appreciable errors in the alkaline pH range. These errors are small below 9 pH and 25° C., but increase appreciably above 25° C. and cause the E.M.F. reading to be too low. Potassium errors are less than 0.005 volt up to 11 pH and 25° C. Lithium and sodium errors may be much greater. It is not recommended that a glass electrode be used for absolute pH measurements above 9 pH and 25° C. in solutions containing appreciable amounts of the above named salts. If measurements of such solutions must be made, it is necessary to calibrate the glass electrode with some suitable secondary electrode, in the solution in question, at the same temperature and pH as subsequent measurements are to be made. A hydrogen gas electrode may be used as a secondary electrode for many solutions, but must not be used in oxidizing or reducing solutions.

If a suitable secondary electrode can be found and the proper correction once established for a specific solution, temperature, and pH, subsequent glass electrode measurements may be corrected by adding the voltage correction to the E.M.F. values in Tables VI, VII, VIII.

ELECTROMETRIC DETERMINATION OF HYDROGEN ION CONCENTRATION

MEASUREMENT OF pH WITH THE ANTIMONY ELECTRODE

The relationships involved in the metal oxide system may be expressed by the following equations:

$$Sb+3H_2O=Sb(OH)_3+3H^++3e^-$$

$$E=E_o-\frac{RT}{3F}\ln\frac{(Sb(OH)_3)(H^+)^3}{(H_2O)^3}$$

The E.M.F. relationships can be expressed in another equation:

$$E=E_o-\frac{RT}{F}\log K_w+\frac{RT}{nF}\log K_s+\frac{RT}{F}\log (H^+)$$

where K_w is the ionization constant of water and K_s is the solubility product of the sparingly soluble metal compound. For the equation to reduce to the form

$$E=constant+\frac{RT}{F}\log (H^+)$$

it is necessary that the activity of the water remain constant and the solution remain saturated with the oxide. For an industrial electrode of moderate accuracy when used in aqueous solutions in contact with air, there is evidence that enough oxide is formed according to the equation $4Sb+3O_2+xH_2O=2Sb_2O_3\cdot xH_2O$, so that further addition of the metal oxide to the aqueous solution is unnecessary.

For an antimony-saturated calomel electrode system used in air-saturated, agitated buffer solutions at 25°C., the following equations apply:

From 3 to 7 pH:	$E=-0.008+0.059pH$
From 7 to 11pH:	$E=\ 0.050+0.051pH$

When involved in low salt concentrations, as in water treatment applications at 25°C., the following equations apply:

From 3 to 6 pH:	$E=-0.024+0.056pH$
From 6 to 8 pH:	*A non-linear relationship*
From 8 to 11pH:	$E=-0.071+0.060pH$

The temperature coefficient of the antimony-saturated calomel electrode system varies with the pH value of the buffer and is of the order of 0.00115 volt per 1°C. at 3 pH, 0.00210 volt per 1°C. at 7 pH, and 0.00344 volt per 1°C. at 12 pH.

Reproducible pH measurements may be made in ordinary solutions to ± 0.15 pH over the pH range of 3 to 11. The electrode is rugged and, since the electrode system is of low resistance, the problem of electrical leakage and pick-up is minimized.

NOTES ON THE ANTIMONY ELECTRODE

Impurities in the metal electrode tend to decrease the stability of the electrode system especially in the acid range. The presence of small amounts of copper is particularly harmful. Antimony of sufficient purity can be obtained by electrolyzing a solution composed of antimony oxide dissolved in hydrofluoric acid.

The E.M.F. -pH relationships of the antimony electrode are influenced by (*1*) the nature of the electrode surface; (*2*) concentration of dissolved air or oxygen; (*3*) agitation at the electrode surface; (*4*) nature and concentration of dissolved salts; and, (*5*) temperature of the system.

The E.M.F. of the electrode system gradually drifts until the surface of the electrode has become etched. Continuous exposure to aqueous solutions containing air results in a deeply etched surface with the possibility of occluding impurities.

ELECTROMETRIC DETERMINATION OF HYDROGEN ION CONCENTRATION

The tendency towards instability in the acid range when the concentration of dissolved oxygen is low, and the failure of the electrode to follow the Nernst equation in the alkaline range when dissolved oxygen is present, is characteristic of the antimony electrode. The extent of the influence of agitation depends upon the pH, the temperature, the nature of the solution, and the concentration of the dissolved oxygen and is more critical in a solution of low salt content.

Dilute solutions of hydrogen peroxide, potassium permanganate, and sodium chromate result in low pH values. Good results have been reported with dilute solutions of sodium sulfide and sulfite. Traces of copper in acid solution cause large deviations and for reliable results the copper content should be below 0.1 part per million. The presence of metals less electropositive than antimony cause a similar behavior. As yet, no systematic study of the possible salt errors of the antimony electrode has been published but there are indications that these errors may be serious with concentrations above one molar.

COMPOSITION AND *pH* OF MacILVAINE'S BUFFER MIXTURES

Cf. T. C. MacIlvaine, *J. Biol. Chem., 49, 183 (1921)*; C. J. Schollenberger, *The Chemist-Analyst, 19 No. 3, 8 (1930).*

Stock solution A, 0.2*M* disodium phosphate: Dissolve 145 g. C. P. clear crystals in 2 liters CO_2-free water. Titrate 10 ml. with 0.1 *N* HCl and a drop of methyl orange indicator to match the tint shown by 30 ml. of a solution containing 2.28 g. C. P. KH_2PO_4 and 1.00 g. C. P. NaCl in 250 ml. H_2O. Adjust solution A to require 20.00 ml. 0.1 *N* HCl in a repeating titration.

Stock solution B, 0.1*M* citric acid: Dissolve 45 g. C. P. clear crystals and dilute to 2 liters. Titrate 10 ml. with 0.1 *N* NaOH (carbonate-free) and phenolphthalein indicator, and adjust solution **B** to require 30.00 ml. in a repeating titration. To preserve solutions **A** and **B**, about 0.1% of toluene may be added.

To prepare the buffer mixtures, measure into a test tube the required volume of solution **A** for the desired *pH*, as shown in the table below, and add sufficient solution **B** to make the total volume exactly 10.00 ml.

pH	ml. A	*pH*	ml. A	*pH*	ml. A	*pH*	ml. A	*pH*	ml. A
2.2	0.20	3.4	2.85	4.6	4.67	5.8	6.05	7.0	8.24
2.4	0.62	3.6	3.22	4.8	4.93	6.0	6.32	7.2	8.70
2.6	1.09	3.8	3.55	5.0	5.15	6.2	6.61	7.4	9.09
2.8	1.58	4.0	3.85	5.2	5.36	6.4	6.92	7.6	9.37
3.0	2.05	4.2	4.14	5.4	5.57	6.6	7.27	7.8	9.58
3.2	2.47	4.4	4.41	5.6	5.80	6.8	7.72	8.0	9.73

ACID—BASE INDICATORS

An acid-base indicator is a weak acid or a weak base, the undissociated form of which has another color and constitution than the iogenic form. An indicator does not change its color from the purely acid to the purely alkaline side at a definite hydrogen concentration, but the color change takes place over a certain range of hydrogen ion concentrations. This range is called the color change interval and is expressed in the term of *pH* (the negative logarithm of the hydrogen ion concentration). A great number of substances show indicator properties although relatively few of them are practically applied for neutralization reactions and *pH* determinations.

COLOR CHANGE AND pH INTERVAL OF THE MOST IMPORTANT INDICATORS

(See also Indicator Chart which follows)

Scientific Name	Trade Name	Solvent	Color		*pH* Interval
			Acid	Basic	
Sodium salt of diphenylaminoazo-*p*-benzenesulfonic acid	Tropeolin 00	Water	Red	Yellow	1.3—3.0
Thymolsulfonphthalein	Thymol blue	Water (+NaOH)	Red	Yellow	1.2—2.8
p-Dimethylaminoazobenzene	Methyl yellow	90% alcohol	Red	Yellow	2.9—4.0
Sodium salt of *p*-dimethylaminoazobenzene-sulfonic acid	Methyl orange	Water	Red	Orange-yellow	3.1—4.4
Tetrabromophenoltetrabromosulfonphthalein	Tetrabromophenol blue	Water (+NaOH)	Yellow	Blue	3.0—4.6
Tetrabromophenolsulfonphthalein	Bromophenol blue	Water (+NaOH)	Yellow	Blue-violet	3.0—4.6
Tetrabromo-*m*-cresolsulfonphthalein	Bromocresol-green	Water (+NaOH)	Yellow	Blue	3.8—5.4
Dimethylaminoazobenzene-*o*-carboxylic acid	Methyl red	Water (+NaOH)	Red	Yellow	4.4—6.2
Dichlorophenolsulfonphthalein	Chlorophenol red	Water (+NaOH)	Yellow	Red	4.8—6.4
Dibromophenolsulfonphthalein	Bromophenol red	Water (+NaOH)	Yellow	Red	5.4—7.0
Dibromothymolsulfonphthalein	Bromothymol blue	Water (+NaOH)	Yellow	Blue	6.0—7.6
Phenolsulfonphthalein	Phenol red	Water (+NaOH)	Yellow	Red	6.4—8.0
Dimethyldiaminophenazinechloride	Neutral red	90% alcohol	Red	Yellow-orange	6.8—8.0
m-Cresolsulfonphthalein	*m*-Cresol purple	Water (+NaOH)	Yellow	Purple	7.4—9.0
Thymolsulfonphthalein	Thymol blue	Water (+NaOH)	Yellow	Blue	8.0—9.6
Phenolphthalein	.....	90% alcohol	Colorless	Red	8.0—9.8
Thymolphthalein	.....	90% alcohol	Yellow	Blue	9.3—10.5
Sodium salt of *p*-nitranilineazosalicylic acid	Alizarine yellow	Water	Yellow	Red	10.1—12.0

It should be emphasized that the intervals as given above hold for aqueous solutions. The characteristics of indicators vary with different solvents; e. g., in mixtures of water and alcohol. Therefore, in the measurement of *pH* in tinctures, a correction should be applied for the effect of the medium.

ACID—BASE INDICATORS

Preparation and Properties of Indicator Solutions.—A useful concentration of the indicator in the solution is of the order of 0.05 to 0.1%. Ordinarily the addition of 0.1 to 0.2 cc. of such an indicator solution to 10 cc. of the liquid to be investigated will give satisfactory results. Five of the indicators listed above (tropeolin 00, methyl yellow, methyl orange, methyl red, and neutral red) behave like weak bases, whereas the others behave like weak acids. The sulfonphthaleins originally introduced by Clark and Lubs (1917) and later extended by others (especially Barnett Cohen), are all indicators with very sharp color changes from yellow to intense red, blue or purple. Bromophenol blue in its tranition interval shows a so-called "*dichroism*," the color of the indicator depending upon its concentration and the depth of the layer observed. It appears blue in a thin layer of the solution, and purple when viewed through a greater depth. In the colorimetric determination of *pH* this dichroism is very objectionable. Often the solution under examination contains substances which affect the light absorption of the indicator (alcohol, alkaloids; in alcoholic medium the color change is from yellow to blue); moreover, the indicator cannot be used in turbid solutions. When a layer of the liquid is viewed only a small amount of light from the bottom of the cell reaches the eye. Most of the light enters the cell through the side, is reflected by the particles and thus produces the effect of a thin layer of liquid with the accompanying blue color. A comparison of the color with that of the indicator in a clear buffer solution is scarcely possible, for a thin layer of fluid would have to be taken. Fortunately, Harden and Drake (*Jour. Am. Chem. Soc.*, 51, 562 (1929)) found that tetrabromophenol - tetrabromosulfonphthalein is a good substitute for bromophenol blue since it shows the same color change without the objectional dichroism.

As a rule, water can be used as a solvent for indicators, but methyl yellow and the phthaleins must be dissolved in 90% alcohol. The various sulfonphthaleins and methyl red must be neutralized with sodium hydroxide before they are soluble in water. The former behave as dibasic acids, the indicator properties being determined by the magnitude of the second ionization constant. For most purposes it is sufficient to neutralize the strong sulfonic group, except that in cases where the *pH* of practically unbuffered solutions have to be measured, then more attention must be paid to the proper preparation of the indicator solution. To prepare an indicator solution, 100 mg. of the indicator are rubbed in an agate mortar with the amount of 1/20*N* sodium hydroxide specified in the table below. After solution of the indicator has taken place, sufficient water is added to make the volume 100 cc. (0.1%) or 200 cc. (0.05%).

Indicator	Molecular Weight	cc. 1/20 *N* NaOH per 100 mg. of Indicator
Thymol blue	466	4.3
Tetrabromophenol blue	986	2.0
Bromophenol blue	669	3.0
Bromocresol green	698	2.9
Methyl red	269	7.4
Chlorophenol red	423	4.7
Bromothymol blue	624	3.2
Phenol red	354	5.7
m-Cresol purple	382	5.2

Colorimetric Determination of *pH* with Selected Buffer Mixtures.—The colorimetric determination of *pH* is based upon the principle that if an indicator be added to different solutions and it assumes the same transition shade, then such solutions are supposed to have the same *pH*. To the solutions, the *pH* of which is to be determined, a measured volume of a suitable indicator

is added and the color compared with that of the same indicator in solutions of known *pH*. The method, therefore, is a comparison procedure the accuracy of which depends primarily upon the correctness of the standard reference solutions. The *pH* of the latter is determined by means of the hydrogen electrode. The standardization according to the potentiometric method is, therefore, the primary procedure upon which the colometric procedure rests. Such standard reference solutions are called "*buffer-mixtures*." Buffer solutions of various compositions have been described in the literature (compare Clark, *The Determination of Hydrogen Ions*, Baltimore, Md., 1928; Kolthoff, *Indicators*, translated by Furman); the most popular set of buffers is that of Clark and Lubs which is given below.

Preparation of Buffer Solutions.—Purity of Materials.

Hydrochloric acid, 0.2 *N* and 0.1 *N*, ordinary C. P. grade prepared and standardized according to the usual volumetric procedure. (Cf. Section on Standard Solutions.)

Sodium hydroxide, 0.1 *N*, prepared carbonate free and standardized according to the usual volumetric procedure.

Potassium acid phthalate, $KHC_8H_4O_4$, $M=204.2$. The C. P. product commercially available is of sufficient purity. It can be recrystallized from water and dried at 110-120°C. The purity of the material must be checked by a titration with standardized sodium hydroxide using phenolphthalein or thymol blue as an indicator. A 0.1 molar solution of the salt is prepared as a stock solution.

Monopotassium phosphate, KH_2PO_4, $M=136.2$. The C. P. salt commercially available is recrystallized twice from water and dried at 110-120°C. A 0.1 molar solution of the salt is prepared as a stock solution.

Potassium chloride, KCl, $M=74.6$, The C. P. product is recrystallized twice from water and is dried at 120°.

Boric acid, H_3BO_3, $M=62.0$. The C. P. product is recrystallized from water and dried in the air. A 0.1 molar solution of boric acid in 0.1 molar potassium chloride is prepared as a stock solution.

COMPOSITION AND pH OF CLARK AND LUBS BUFFER MIXTURES AT 20°C.

Measurement of pH.—If the approximate value of the *pH* of a solution is unknown, the order of its magnitude must first be approximated in order to select the correct indicator for a more accurate evaluation. As a rule, a few simple tests will supply this information. For example, if a solution remains colorless after the addition of a drop of phenolphthalein, it indicates that the *pH* of the solution is less than 8.0 (cf. table of indicators); if now a second test is made with methyl orange or bromophenol blue and the solution assumes the alkaline color of the indicator, it means that the *pH* is greater than 4.5. Therefore, such a solution has a *pH* value between 4.5 and 8.0. A few more tests with methyl red (*pH* interval 4.4 to 6.0); bromothymol blue (*pH* interval 6.0 to 7.2) and phenol red (*pH* interval 6.8 to 7.0) would serve to show the approximate *pH* value and suggest which indicators should be used for the exact determination. Instead of testing small amounts of the liquid with indicator solutions, indicator papers (litmus, congo, phenolphthalein, thymol blue, etc., papers) as a rule may be used by application of the spot method.

When the approximate value of *pH* is known, 3, 5, or 10 cc (depending upon the amount of liquid available) are measured out by means of a graduated cylinder and transferred into a test tube of pyrex glass or any other resistant glass. Soft glass should not be used because of the possibility of an alkaline reaction of the glass; the tubes should all be of the same inner size with a diameter of 1.5 cm and a length of 15 cm. A measured amount of the indicator solution is added carefully from a pipette of 1 cc volume which is graduated in 0.01 cc. As a rule, 0.1 to 0.2 cc of 0.05% indicator solution to 10 cc liquid will be the proper amount. Then some buffer solutions (4 to 6 cc) the *pH* of which overlaps that of the unknown are taken and treated in exactly the same way. Especially if one-color indicators are used, it is extremely important to add to the unknown and to the buffer solutions exactly the same amount of indicator. The best way of judging the color is to observe, against

ACID—BASE INDICATORS

a white back-ground, the light transmitted through the whole length of the tube. A suitable colorimeter may be used as well, although it is not necessary in routine work. Enough reference solutions must be taken so that the color of the unknown falls between two of the series and not beyond them. If buffer solutions are used with *pH* differences of 0.2 respectively, the *pH* of the unknown can be approximated very easily to within 0.1, and with some practice to 0.05. With buffer solutions that differ by 0.1 *pH* unit or less, the *experimental* error can be reduced to 0.01 to 0.02 in *pH*.

INDICATOR CHART

Reprinted by permission of the Eastman Kodak Co.

The pH ranges shown are approximations and are intended to aid in selecting the proper indicator. The first column on the left gives the catalog number for ordering the indicator from the Eastman Kodak Co. The following abbreviations are used: A, amber; B, blue; C, colorless; BG, blue green; BV, blue violet; G, green; O, orange; P, pink; Pu, purple; R, red; V, violet; Y, yellow.

AN OUTLINE FOR QUALITATIVE ANALYSIS

By R. C. Hummell, Ph. D.

Preparation of Solution for Metal Analysis

A. If the sample to be analyzed is already in solution, acidify with nitric acid unless it is already acid.

B. If the sample is solid and metallic in appearance indicating a metal or alloy, dissolve in dilute nitric acid. (A few metals and alloys dissolve better in hydrochloric acid.) If a white residue remains from the treatment with nitric acid filter it off and dissolve it in boiling concentrated hydrochloric acid and test this solution for tin and antimony only.

C. If solid and non-metallic try to dissolve the sample first with water (cold and boiling), then if a residue is left, filter it and next try dilute nitric and hydrochloric acids successively, then concentrated hydrochloric acid, then aqua regia and if a residue still remains it must be filtered off and treated as an insoluble material.

D. Insoluble Material. (Cf. note following D2.) If a platinum crucible is available, mix the powdered "Insoluble" with about ten times its bulk of a mixture of equal parts of sodium carbonate and potassium carbonate and then fuse in the platinum crucible using a blast burner or Meeker burner. If a platinum crucible is not available an iron crucible may be substituted in which case a piece of sodium hydroxide about twice the size of a pea is substituted for the potassium carbonate. Heat the crucible and its contents for five minutes after a clear fusion is obtained. Then pour the melt on to a small piece of sheet-iron to solidify. Digest this with water until entirely disintegrated. Filter and treat the residue as directed in D1 and the filtrate as in D2.

D1. Dissolve the residue in dilute nitric acid and test for metals as outlined.

D2. Add the filtrate from digestion of the fusion above to the solution prepared especially for acid analysis as given in the tests for acid radicals.

Note. If the "insoluble" is white, before fusion its solubility in ammonium hydroxide or ammonium acetate should be tested as it might be silver chloride or lead sulfate and the ammonium hydroxide and ammonium acetate are solvents respectively for these.

All of the solutions prepared according to the directions given above, except D2 are to be analyzed for metals as directed in the following outline.

GROUP I

Add cold dilute hydrochloric acid drop by drop until precipitation is complete. Precipitate: $PbCl_2$, HgCl, AgCl. Filter. Wash with cold water. Save the filtrate to test for the subsequent groups.

Precipitate. Boil with 10 cc of water. Filter while hot.

Filtrate—$PbCl_2$. Add $K_2Cr_2O_7$ or K_2CrO_4 solution. Yellow ppt.—$PbCrO_4$ indicates Pb.	Precipitate—HgCl and AgCl Pour 5 cc NH_4OH over the precipitate.	
	Residue—If black indicates Hg.	Filtrate—Just acidify with HNO_3. White ppt. of AgCl indicates Ag.

GROUP II

To the filtrate from Group I add 1 cc of concentrated HNO_3 and evaporate just to dryness being careful near the end of the evaporation not to overheat any of the dry residue. Dissolve this residue with 2½ cc of concentrated HCl and 5 cc of water. Heat to boiling and pass H_2S into the solution for 5 minutes Dilute to 40 cc and again pass in H_2S for 5 minutes. Filter 2 cc of this solution and dilute it to 5 cc and test with H_2S. If no precipitate forms then filter the main solution. If a precipitate does form, dilute the main solution to 100 cc and again pass in H_2S until precipitation is complete. Filter. Wash with hot water. Save the filtrate for subsequent groups.

AN OUTLINE FOR QUALITATIVE ANALYSIS

Precipitate: Sulfides of Hg, Pb, Bi, Cu, Cd, As, Sb, and Sn. To the precipitate add 15 cc of 2*N* NaOH, warm and stir. Filter. Wash with hot water.

Residue—Sulfides of Hg, Pb, Bi, Cu and Cd. Boil with 15 cc dilute HNO_3. Filter. Wash.

Residue—HgS. Dissolve in aqua regia. Boil out excess Cl_2. Add $SnCl_2$. A white or gray ppt. indicates Hg.

Filtrate—Make just alkaline with NaOH, then add 7 cc of 6*N* NaOH in excess. Warm and stir. Filter.

Filtrate—Na_2PbO_2. Acidify with acetic acid. Add K_2CrO_4. Yellow ppt. $PbCrO_4$. Indicates Pb.

Precipitate—Hydroxides of Bi, Cu, Cd. Dissolve in dilute HNO_3. Make strongly alkaline with NH_4OH. Filter.

Precipitate—$Bi(OH)_3$. Treat on filter with freshly prepared sodium stannite solution.* Immediate black coloration indicates Bi.

Filtrate—Ammoniated salts of Cu and Cd. If solution is deep blue Cu is present. If doubtful take a small portion and make acid with acetic acid, then add potassium ferrocyanide solution. Filter. A red ppt. on the white filter indicates Cu and is $Cu_2Fe(CN)_6$. If Cu is present add KCN to the main bulk of the filtrate until the solution is decolorized. Pass in H_2S. A yellow ppt. indicates Cd. If Cu is not present omit the addition of KCN.

Filtrate—Sodium thio-salts of As, Sb, Sn. Make just acid with acetic acid. Filter. Discard filtrate. Precipitate—Sulfides of As, Sb, Sn. Treat the well drained ppt. with 10 cc of hot conc. HCl. Stir thoroughly but do not boil. Dilute with 5 cc of water and filter.

Residue—Sulfides of As. Dissolve in NH_4OH adding a few drops of H_2O_2. Add magnesia mixture. A fine feathery ppt., slow in forming, indicates As and is $MgNH_4AsO_4$

Filtrate—Chlorides of Sb and Sn. Evaporate to a few cc. Place a few drops of this solution on a silver coin or platinum foil. Place a piece of tin so it touches the solution on the coin and the coin itself. A black coating on the coin indicates Sb. The main bulk of the solution is heated and some metallic iron added. After this reacts for a minute or so, decant off the clear solution and add to it $HgCl_2$. A white ppt. of $HgCl$ or a gray ppt. of Hg indicates Sn.

*Sodium stannite solution is prepared by adding sodium hydroxide solution to a few cc of stannous chloride solution until the white precipitate which is formed at first just dissolves.

GROUP III

Evaporate the filtrate from Group II to 10 cc. Test 1 cc for phosphates by adding to it 2 cc of conc. HNO_3 and 2 cc of ammonium molybdate reagent. Warm and allow to stand for at least 5 minutes. A fine yellow precipitate indicates phosphates. If phosphates are present remove them from the main solution as follows. First make the solution neutral with NH_4OH then add 3 cc of acetic acid and 5 cc of 50% ammonium acetate solution. Add to this sufficient $FeCl_3$ solution until no more precipitate forms and the solution becomes reddish in color. Dilute to 70 cc and boil until a condition is obtained where the precipitate on settling leaves the solution free from the reddish brown color. If necessary add more ammonium acetate to get this result. Filter.

Precipitate—Phosphates of Fe and possibly Al and Cr. Test for Al and Cr. Add 10 cc of dilute NaOH and 1 g Na_2O_2 to the ppt. Boil and then filter. Discard the ppt. Divide the filtrate into two parts.

First portion—Make acid with HCl, then alkaline with NH_4OH. White flocculent ppt. indicates Al.

Second portion—Make acid with acetic acid, then add lead acetate. Yellow ppt. indicates Cr.

Filtrate—Group III except possibly Fe, Al and Cr. Analyze according to procedure given for Group III with phosphates absent.

GROUP III

Phosphates Absent.

If phosphates are absent, or after removing them if present, add 1 g of NH_4Cl to the solution, then make it alkaline with NH_4OH and pass in H_2S to complete precipitation. Filter. Wash. Save filtrate for subsequent groups.

AN OUTLINE FOR QUALITATIVE ANALYSIS

Precipitate—Sulfides of Co, Ni, Mn, Zn, Fe and the hydroxides of Al and Cr. Digest cold with 25 cc of 1 **N** HCl. Filter. Wash.

Residue—CoS and NiS. Make a borax bead test on this residue. Blue bead indicates Co. Brown bead indicates Ni. Then dissolve residue in aqua regia and divide into two parts.

First portion—Add $NaHCO_3$ (solid) until effervescence ceases. Then add H_2O_2; development of deep green color indicates Co.

Second portion — Make alkaline with NH_4OH and add dimethylglyoxime. A red or scarlet ppt. indicates Ni.

Filtrate—Chlorides of Fe, Mn, Al, Cr and Zn. Evaporate to about 5 cc. add 5 cc of 30% NaOH solution and 3 cc of H_2O_2 and boil. Filter. Wash.

Precipitate — Hydroxides of Fe and Mn. Make a Na_2CO_3 bead test on this ppt. for Mn using a little $KClO_3$ in the bead in the last part of the fusion. Bluish-green bead indicates Mn. Dissolve the remainder of the ppt. in HCl and add NH_4CNS solution. Blood red color indicates Fe. If iron was added to remove phosphates a little of the original sample can be tested for Fe by boiling with HCl and testing with NH_4CNS.

Filtrate—$NaAlO_2$, $NaCrO_4$, Na_2ZnO_2. Make acid with HCl, then just alkaline with NH_4OH. Filter.

Precipitate — $Al(OH)_3$. This ppt. should be white and flocculent. If in doubt remove the paper from the funnel, roll it up, drop 2 drops of dil. HCl down the top, then 2 drops of dil. $Co(NO_3)_2$ soln. Coil a wire around the rolled paper and burn to an ash. Blue ash indicates Al.

Filtrate—Make acid with acetic acid. Add 2 cc ammonium acetate solution, then 2 cc of $BaCl_2$ solution. Filter.

Precipitate — Yellow ppt. indicates Cr. If a white ppt. formed it is to be disregarded.

Filtrate—Pass in H_2S. A white or gray ppt. composed of fine curdy particles indicates Zn. A milky suspension but not curdy is due to sulfur.

GROUP IV

Make the filtrate from Group III acid with acetic acid and evaporate to 10 cc. Filter if necessary and discard the precipitate. To the filtrate or clear solution add NH_4OH until alkaline, then add 15 cc of 95% ethyl alcohol and 15 cc of ammonium carbonate solution. Filter. Wash. Save the filtrate for subsequent group.

Precipitate—Carbonates of Ba, Ca, Sr and Mg. Dissolve in acetic acid. Add 5 cc of ammonium acetate solution and about 10 cc of potassium dichromate solution. Filter.

Precipitate—$BaCrO_4$. Moisten this ppt. with HCl and make a flame test with a platinum wire. Green flame indicates Ba.

Filtrate—Acetates of Sr, Ca, Mg and excess $K_2Cr_2O_7$. Make alkaline with NH_4OH and add 5 cc of alcohol. Filter.

Precipitate—$SrCrO_4$ and possibly some $CaCrO_4$. Boil with $(NH_4)_2CO_3$ and $(NH_4)_2C_2O_4$. Filter. Discard filtrate. Treat residue with acetic acid. Filter.

Residue—CaC_2O_4

Filtrate — Add Na_2SO_4 solution. White ppt. indicates Sr.

Filtrate—Ca and Mg salts. Add $(NH_4)_2C_2O_4$ solution. Filter.

Precipitate — CaC_2O_4 and possibly some MgC_2O_4. Treat with dil. H_2SO_4. Filter. To the solution add 5 cc of alcohol. Ppt. indicates Ca.

Filtrate — Add Na_2HPO_4 solution. White ppt. indicates Mg.

GROUP V

Evaporate the filtrate from Group IV to dryness. Heat the dry residue just short of a red heat until all of the ammonium salts have been expelled. Cool. Moisten with HCl and make a flame test with a platinum wire. An in-

tense yellow flame indicates Na. A pale violet flame indicates K. If flame is intense yellow view it through a small bottle containing a 10% solution of $KCr(SO_4)_2$ or several thicknesses of cobalt glass. A red flame as thus viewed indicates K. To test for NH_4^+—Take about 1 g of the original sample in a small beaker, add sodium hydroxide solution in excess, cover the beaker with a watch glass containing on the under side a moist piece of red litmus paper. Warm and observe the litmus paper. If it changes slowly and evenly from red to blue, NH_4^+ is present.

ACIDIC CONSTITUENTS

Detection of Groups of Acidic Constituents.

The following acid ions are provided for in this procedure: Chlorides, bromides, iodides, ferrocyanides, ferricyanides, thiocyanates, sulfates, sulfites, thiosulfates, chromates, fluorides, silicates, oxalates, tartrates, sulfides, carbonates, phosphates, borates, nitrates, nitrites, acetates, and permanganates.

Preliminary Examination. Detection of some acid radicals.—

1. Moisten with concentrated H_2SO_4 and observe results both cold and when heated.
   (a) Tartrates heated with H_2SO_4 turn brownish black and give odor of burnt sugar.
   (b) Carbonates give off colorless, odorless gas which will cloud a drop of lime water held over the reacting materials.
   (c) Some sulfides readily give off H_2S with H_2SO_4 and this can be detected by the odor or the darkening of a piece of paper moistened with $Pb(C_2H_3O_2)_2$.
   (d) Nitrites will give off brown fumes immediately.
   (e) Bromides will oxidize slowly with the formation of free bromine which can be recognized by the reddish brown color of the gas.
   (f) Iodides will liberate free iodine which is recognized by the purple color.
   (g) Sulfites will liberate SO_2 which is colorless but has the characteristic, sharp pungent odor of burning sulfur.
   (h) Oxalates, when heated with H_2SO_4, give off CO and CO_2. The CO can be ignited.
   (i) Thiosulfates liberate SO_2 and form a residue of sulfur.
   (j) Acetates heated with H_2SO_4 liberate acetic acid which is recognized by the odor of vinegar.

2. Moisten a gram of the solid in an evaporating dish (if Cu and Ba are absent) with conc. H_2SO_4, add a few drops of alcohol and ignite the alcohol. A green flame indicates borates. If Cu or Ba are present use a test tube fitted with a stopper and short constricted outlet tube instead of the evaporating dish. In either case heat to help expel the volatile ethyl borate which will burn in the alcohol vapor with a green flame.

3. Add cold dilute HCl solution. An immediate evolution of brown fumes indicates nitrites.

4. If the sample is yellow or deep purple in color heat with dilute alcohol.
   (a) If the yellow color is changed to green and the metal analysis shows Cr present then chromates are present.
   (b) If the purple color is discharged and manganese was found in the metal analysis this test indicates the presence of permanganates.

5. The test for phosphates was made at the beginning of the analysis for Group III and need not be repeated at this point.

Preparation of Special Solution for Detection of Acidic Groups.—Take about 2 g of the powdered sample and boil with 25 cc of a saturated solution of sodium carbonate for 15 minutes. If a fusion was made in the analysis for metals, add the water extract from D2, dilute to 40 cc and filter. Use this solution for the following acid tests. Take 20 cc of this "prepared solution," make acid with dilute acetic acid and then add 1 cc of the acid in excess, boil gently to expel CO_2 and any H_2S which might be present. Test the vapor for H_2S by holding a piece of paper moistened with lead acetate in the vapors evolved during the boiling. A dark coloration

AN OUTLINE FOR QUALITATIVE ANALYSIS

indicates sulfides. If a white gelatinous precipitate forms at this point test it for silicic acid by the microcosmic bead test as follows: Filter, ignite the residue in a crucible, make a bead of microcosmic salt, dip it in the residue and fuse. If undissolved particles float in the bead while melted, Si is indicated. Make the filtrate from the procedure above neutral or slightly alkaline. Add a mixture of $Ca(NO_3)_2 + Ba(NO_3)_2$ solution and filter. Precipitate see Group I. Filtrate see Group II.

Precipitate—Group I acids. Add 5 cc acetic acid, warm and stir. Filter. The filtrate contains $CaHPO_4$, $CaC_4H_4O_6$. This filtrate is discarded as these groups were tested for previously.
Residue—CaF_2, CaC_2O_4, $BaSO_4$, $BaCrO_4$. Treat with 5 cc dilute HCl. Filter.

Precipitate—CaF_2, $BaSO_4$. Divide into two parts.

First portion — Add conc. HCl and boil for a few minutes. Dilute White ppt. indicates SO_4''.

Second portion — Dry over a low flame. Mix with a little sand. Place in a test tube and moisten with conc. H_2SO_4. Hold a film of water in a glass loop just above the mixture and warm. A ppt. in the water film indicates fluorides.

Filtrate—If yellow, chromates are present. As confirming this recall whether the filtrate from Group I metals was yellow and then turned green when H_2S was passed in and a formation of colloidal sulfur formed. To test for oxalates take 2 cc of the prepared solution, boil with a small excess of acetic acid, filter, make alkaline with NH_4OH, add $Ca(NO_3)_2$, filter, treat with 5 cc acetic acid, filter, wash. Then treat with dilute H_2SO_4, warm and add dilute $KMnO_4$ solution. Color destroyed indicates C_2O_4''.

Filtrate—Sodium salts of Group II. Make exactly neutral with HNO_3. Add $Zn(NO_3)_2$ solution. Filter.

Precipitate—$Zn_3(FeC_6N_6)_2$ brownish yellow and $Zn_2Fe(CN)_6$ white. Divide into 2 parts.

First portion—Dissolve in NH_4OH. Brown coloration indicates $FeC_6N_6)''$.

Second portion—Dissolve in HCl and add $FeCl_3$ solution. Deep blue indicates $(FeC_6N_6)''$.

Filtrate—Take out a few drops to test for CNS.

To the few drops add $FeCl_3$ soln. Blood red color that remains on heating indicates CNS.

To the remainder of the solution add HNO_3 until acid and then add $AgNO_3$ solution. Filter. Discard filtrate. Add "chloride reagent" (described below). **Filter.

Filtrate—Acidify with HNO_3. White ppt. indicates chlorides.

Precipitate—Place a small amount in a test tube. Add 2 cc CS_2 or CCl_4, then some chlorine water (see below)*. Shake vigorously. Purple color in CS_2 indicates iodine. Brown color in CS_2 indicates bromine. If purple at first, continue to add Cl water until the purple color is discharged. If the brown color presists both iodine and bromine are present.

*Chlorine water for this test should be freshly prepared by adding one or two small crystals of $KClO_3$ to a few cc of dilute hydrochloric acid and then warming the solution.

**Chloride Reagent: Dissolve 1.7 grams of $AgNO_3$ and 25 grams of KNO_3 in an amount of water less than a liter, add 17cc of conc. NH_4OH, and dilute to a liter.

OTHER TESTS FOR ACIDIC CONSTITUENTS

Nitrates—If iodides, bromides, ferrocyanides, ferricyanides, chromates and nitrites are absent, take 2 cc of the "Prepared solution," make just acid with acetic acid, boil, filter if any precipitate forms, add 3 cc of ferrous sulfate solution, then tip the test tube to an angle of 45° and slowly pour a few cc of concentrated H_2SO_4 down the side of the tube. Bring the tube back to an upright position without stirring the contents. A brown ring forming at the

junction of the two layers indicates NO_3'. If any of the acids which interfere with test and which are mentioned above are present they can be removed as follows: make 5 cc of the "prepared solution" as nearly neutral as possible (do not permit the solution to become acid) with acetic acid, boil with 5 cc $(NH_4)_2SO_4$ solution. This removes nitrites. Acidify the boiled solution with H_2SO_4 and add $AgSO_4$ solution which removes Br', I', $Fe(CN)_6'''$ and $Fe(CN)_6''''$. Filter. To the filtrate add Na_2SO_3 and allow to stand for a few minutes. This reduces the chromates. Boil to expell SO_2, then make alkaline with NH_4OH to precipitate Cr. Filter and test the filtrate as directed above for nitrates $(NO_3)'$.

Sulfides—Some sulfides are left in the residue from boiling the "prepared solution" with acetic acid and do not evolve H_2S in this step. If this residue is placed in a test tube with some sulfur-free zinc and heated with HCl the H_2S will be liberated and can be detected with lead acetate paper.

Phosphates — Arsenates, arsenites, chromates and permanganates are usually detected in the course of the metal analysis.

A few unusual interfering combinations may be met with which because of the nature of this treatise are not discussed.

FLAME TESTS

The substance is heated on a piece of charcoal with a blow-pipe, or held in the outer flame of a Bunsen burner on a loop of platinum wire.

Blue:— *Azure*, Pb, Se, $CuCl_2$ or other copper compounds that have been moistened with hydrochloric acid.
Light blue, As and some of its compounds.
Greenish blue, $CuBr_2$, Sb.

Green:— *Emerald green*, copper compounds other than the halides.
Blue-green, phosphates when moistened with H_2SO_4, B_2O_3.
Faint green, Sb and NH_4 compounds.

White:— *White-green*, Zn.

Red:— *Carmine*, Li compounds. Masked by Ba or Na.
Scarlet or *Crimson*, Sr compounds. Masked by Ba.
Yellow-red, Ca compounds. Masked by Ba.

Violet:— K compounds other than borates, phosphates and silicates. Masked by Na or Li.
Purple-red given by K in the presence of Na when viewed through a blue glass, the blue glass cutting out the yellow caused by Na. Rb and Cs are the same as K compounds.

Yellow:—Na compounds even in small traces. *Caution*—Most compounds contain traces of Na which will color the flame. The appearance of a yellow flame is not a test for Na unless it persists and is not perceptibly increased in intensity on the addition of about 1% of NaCl to the dry compound.

BEAD TESTS

A clear bead is made by fusing a little borax or microcosmic salt on a loop of platinum wire. This bead is touched to the dry unknown material and again held in the flame of a Bunsen burner. The outer part of the flame is the oxidizing flame, while the inner cone is the reducing flame. The abbreviations used below are h., hot; c., cold; *h. c.*, hot or cold; *s.*, saturated; *n. s.*, not saturated; and *sprs.*, supersaturated.

Color of the Bead	Borax Bead, $Na_2B_4O_7 \cdot 10H_2O$		Microcosmic Salt Bead, $NaNH_4HPO_4$	
	Oxidizing Flame	Reducing Flame	Oxidizing Flame	Reducing Flame
Colorless	*h.c.*: Al, Si, Sn, Bi, Cd, Mo, Pb, Sb, Ti, V, W. *n.s.*: Ag, Al, Ba, Ca, Mg, Sr.	Al, Si, Sn, alk. earths and earths. *h.*: Cu. *h.c.*: Ce, Mn.	Si (undissolved) Al, Ba, Ca, Mg, Sn, Sr. *n.s.*: Bi, Cd, Mo, Pb, Sb, Ti, Zn.	Si (undissolved) Ce, Mn, Sn. Al, Ba, Ca, Mg, Sr (*sprs.*, not clear)
Gray and Opaque	*sprs.*: Al, Si, Sn.	Ag, Bi, Cd, Ni, Pb, Sb, Zn. *s.*: Al, Si, Sn. *sprs.*: Cu.	*s.*: Al, Ba, Ca, Mg, Sn, Sr.	Ag, Bi, Cd, Ni, Pb, Sb, Zn.

ORGANIC REAGENTS FOR INORGANIC ANALYSIS

Compiled by

WAYNE E. WHITE, ALUMINUM COMPANY OF AMERICA

with the assistance of

Alfred W. Scott, T. H. Whitehead, University of Georgia, Athens; H. P. Lankelma, Western Reserve University, Cleveland, Ohio; Walter E. Thrun, Valparaiso University, Valparaiso, Ind.; H. B. Riffenburg, Virginia Polytechnic Institute, Blacksburg; John E. Vance, Yale University, New Haven, Conn.; and A. H. Bushey, Aluminum Research Laboratories, New Kensington, Penn.

Abbreviations used in the table: AcOH-acetic acid; addn.-addition; alc.-alcohol; alk.-alkaline; amm.-ammonia, ammonium, ammoniacal; aq.-aqueous; colmtc.-colorimetric; conc.-concentrated; concn.-concentration; contg.-containing; detc.-detection; detg.-determining; detn.-determination; dil.-dilute; estn.-estimation; g.-gram; gravmtc.-gravimetric; intfr.-interfere; mcg.-microgram; mg.-milligram; ml.-milliliter; ppm-parts per million; ppt.-precipitate; pptn.-precipitation; qual.-qualitative; quant.-quantitative; reagt.-reagent; recomm.-recommended; satd.-saturated; sepg.-separating; sepn.-separation; sl.-slight; soln.-solution; volmtc.-volumetric; xs.-excess.

References.—The references in some cases do not include a citation of the original publication because the aim has been to be utilitarian rather than historically complete in choice. The following standard works are frequently referred to under abbreviations as follows:

A. P. H. A.—Standard Methods of Water Analysis, Eighth Ed. 1936, published by American Public Health Association (New York City).

A. O. A. C.—Official and Tentative Methods of Analysis of the Association of Official Agricultural Chemists, Fifth Ed. 1940, published by The Association (Washington, D. C.)

C. A.—Chemical Abstracts.

Feigl—Qualitative Analysis by Spot Tests, by F. Feigl, translated by J. Matthews, Second English Ed. 1939, published by Nordemann (New York).

I. C.—Tables of Reagents for Inorganic Analysis, Report of International Committee, 1939, published by Akademische Verlagsgesellschaft (Leipzig).

Prodinger—Organic Reagents Used in Quantitative Inorganic Analysis, by W. Prodinger, translated by S. Holmes, 1940, published by Elsevier Publishing Co., Inc. (New York).

Snell—Colorimetric Methods of Analysis, by Snell and Snell, 1936, published by Van Nostrand (New York).

Yoe I and *Yoe II*—Photometric Chemical Analysis, by J. H. Yoe, Vol. I (1928), Vol. II (1929), published by Wiley (New York).

ACETATE

o-NITROBENZALDEHYDE is used in freshly prepd. satd. soln. in 2 *N* NaOH. Unknown is heated with $Ca(OH)_2$ or $CaCO_3$ to form acetone if acetate is present; the acetone is detected by a blue coloration (due to formation of indigo) on filter paper moistened with reagt. Specific. Recomm. (*I. C.*) *Feigl, p. 331.*

ALUMINUM

AURIN TRICARBOXYLIC ACID, AMM. SALT (ALUMINON), 0.1% aq. soln., forms a red lake with $Al(OH)_3$. Extensively used for detc. and colmtc. detn. (0.01–1.0 mg.). Optimum lake formation at pH 4.5 to 6.0; dil. HCl soln. buffered with amm. acetate, elevated temp. After cooling, satd. $(NH_4)_2CO_3$ added to raise pH to 7.1–7.3 which decolorizes xs. reagt. Detc. Al in baking powders, cf. *A. O. A. C., p. 190.* Colmtc. detn. Al in alloys, in tissue, and in water, cf. *Snell pp. 260–6.* Fe

(III) and Cr (III) give violet and red colors, resp., but these intfr. may be avoided by extraction of Al as aluminate. Much PO_4 intfr. For Al in foods cf. Cox et al., *Ind. Eng. Chem.* **24**, *403* (*1932*). For test paper, absorb soln. of 0.1% reagt. and 1.0% amm. acetate in filter paper, dry, add drop of acid test soln. After about one minute, expose to ammonia vapors to get rose pink of Al lake. W. E. Thrun, *J. Chem. Education* **14**, *281* (*1937*). Reagt. recomm. (*I. C.*)

SODIUM ALIZARIN SULFONATE (ALIZARIN S), 0.1 to 1.0% aq. soln., is used for detc. by spot and test tube methods, and also for colmtc. detn. In the latter case starch glycerite is useful to prevent pptn.; cf. Thrun, *Ind. Eng. Chem.*, (*Anal. Ed.*) **2**, *8–9* (*1930*). The reagt. is added to a sl. acid soln. which should contain between 0.005 and 0.05 mg. Al; after standing, the soln. is made more acid with AcOH to obtain a red coloration. Fe, Cu, Co, and Mn must be absent. For the spot test cf. *Feigl, pp. 115.* For the colmtc. detn. cf. *Snell, pp. 259–60; Yoe I, pp. 119–20.* An alc. soln. of **ALIZARIN** may be used in much the same way as the alizarin S; the former may be used for impregnating paper for Al tests; cf. *Feigl, p. 116.* Recomm. (*I. C.*).

ERIOCHROMCYANINE R, 0.1% aq. soln., when used in a soln. contg. AcOH at pH 4.6 to 5.6 gives a bluish-red color with Al; in the absence of Al, the color is orange. Fe, Mn, Mg, much PO_4 intfr. It may also be used for a spot test, cf. Eegriwe, *Z. anal. Chem.* **76**, *438–43* (*1929*), or for colmtc. estn., cf. *Snell, pp. 271–3.* Recomm. (*I. C.*).

8-HYDROXYQUINOLINE (OXINE), in dil. AcOH soln., may be used to separate Al quantitatively from Mg and Be by pptn. in acetic acid-acetate soln.; the ppt. may be dried at 110° C. and weighed for detn. of Al, or may be ignited and weighed as the oxide; when the ppt. is small the detn. is better made by titration with $KBrO_3$; cf. Berg. *Z. anal. Chem.* **70**, *341; ibid.* **71**, 171 (*1927*), *et al.* There are many references to the use of this reagt. in the detn. of Al and other metals; cf. *Hiliebrand and Lundell, p. 114 ff.* and *C. A.* indexes. For the colmtc. detn. the Al hydroxyquinolate is pptd. and coupled with diazotized sulfanilic acid; cf. *Snell, p. 267.*

MORIN, satd. methyl alcohol soln. In a neutral or sl. acid soln., minute amounts of Al give a green fluorescence in ultraviolet light; cf. *Feigl, p. 113.* For adaptation to quant. method and discussion of intfrnces., cf. White and Lowe, *Ind. Eng. Chem.*, (*Anal. Ed.*) **12**, *229–31* (*1940*). Recomm. **QUERCETIN** used in manner similar to Morin said to be satisfactory, cf. *C. A.* **36**, *363* (*1942*).

UREA may be used in hot acid soln. which causes its slow hydrolysis and consequent pptn. of basic Al salts in presence of sulfate or succinic acid. Ppt. may then be ignited to oxide. Ppts. thus formed are easily filtered and free from contamination. Willard and Tang; *Ind. Eng. Chem.*, (*Anal. Ed.*) **9**, *357–63* (*1937*).

AMMONIUM

SILVER NITRATE, MANGANESE NITRATE and **BENZIDINE.** A soln. of $AgNO_3$ and $Mn(NO_3)_2$ made 0.1*M* in respect to each salt is neutralized to sl. ppt. with dil. NaOH. The soln. is then filtered and kept in dark bottle. Additional hydroxyl as from NH_3 collected on filter paper moistened with this soln. gives black or gray spot which may be intensified by formn. of blue coloration on addn. of benzidine soln. in AcOH. This test may be highly sensitive. *Feigl, p. 154.* Recomm. (*I. C.*).

SILVER NITRATE AND FORMALIN reagt. is prepared by mixing 10 ml. of 20% silver nitrate soln. with 5 drops of 40% formalin and a few drops of dil. NaOH soln., filtering off any ppt. which may form. The filtrate is immediately absorbed upon strips of filter paper. Ammonia vapor causes the treated filter paper to turn gray or black; the test paper is compared with a blank left exposed to air. **TANNIC ACID** may be substituted for the formalin. A test is obtainable with as little as 0.0001 mg. NH_3; cf. *Feigl, p. 154.* The color may be produced in soln. and used for estn. of NH_3; cf. *Snell, p. 659*; cf. also K. G. Makris, *Z. anal. Chem.* **81**, *212–4* (*1930*); *ibid.* **84**, *241–2* (*1931*). The $AgNO_3$—HClIO reagt. recomm. (*I. C.*).

ORGANIC REAGENTS FOR INORGANIC ANALYSIS

p-**NITROBENZENEDIAZONIUM CHLORIDE (RIEGLER'S REAGENT)** is prepared by diazotization of *p*-**NITRANILINE.** The test may be made on a spot plate by using a drop of neutral or sl. acid unknown soln., adding a drop of reagt. and a little piece of solid CaO. In the presence of as much as 0.0007 mg. NH_3 a red zone is produced around the CaO; cf. *Feigl, p. 152.* Recomm. (*I. C.*).

HEMATOXYLIN, in alc. soln. for impregnating paper. NH_3 gives a red to bluish-red color; cf. G. Gutzeit, *Helv. Chim. Acta* **12,** *730 (1929).*

PHENOL AND SODIUM HYPOCHLORITE, 4% aq. soln. of the former and 5% aq. soln. of the latter. A blue color results when the two reagts. are mixed and warmed in the presence of as little as 0.0001 mg. of ammonia as the salt. The color may be used for estimating the amount of ammonium. The accuracy of the detn. is less than with the Nessler reagt. but the method requires only 4 minutes; Ca does not intfr.; xs. free acid must be neutralized; cf. *Snell, p. 658.* **CHLORAMINE T** may be used instead of NaOCl as a source of Cl; to 2 ml. of sample add 1 ml. of phenol soln. (25 g. phenol in 50 ml. 40% NaOH and dild. to 100 ml.) and 3 ml. 5% Chloramine T. Ammonia free water must be used. After heating mixture for 10 min. the blue color is compared to standards, cf. Crismer, *Bull. soc. chim. biol.* **19,** *1000–9 (1937); C. A.* **31,** *7796 (1937).*

THYMOL, 25% soln. in alcohol. To 5 ml. of the test soln. are added 1 ml. of the reagt. with mixing, then 12 ml. of bromine water and 6 ml. of 2*N* NaOH. After 2 or 3 minutes, xylene is added, the mixture shaken and color observed in the xylene layer; cf. Lapin and Hein, *Z. anal. Chem.* **98,** *236–40 (1934).* For colmtc. detn. of NH_3, cf. Hansen and Nielsen, *J. Biol. Chem.* **131,** *309 (1939).*

ANTIMONY

RHODAMINE B, 0.01% aq. soln., is suitable as a spot or test tube test to detect Sb in the presence of Sn. The Sb is oxidized to pentavalent form by the addn. of KNO_2 to the acidified soln. and, on the addn. of a few drops of reagt., the soln. color changes from bright red to violet. Bi, Hg, and tungstate give similar coloration; cf. Eegriwe, *Z. anal. Chem.* **70,** *400–3 (1927); Feigl, p. 56.* For colmtc. detn. of 0.1 to 300 mcg. Sb, cf. W. G. Frederick, *Ind. Eng. Chem., (Anal. Ed.)* **13,** *922–4 (1941).* Recomm. (*I. C.*).

POTASSIUM IODIDE and **PYRIDINE,** in acid solns., give a yellow color or ppt. in the presence of Sb. As and Sn do not intfr.; cf. Clarke, *Analyst* **53,** *373 (1928).* The color may be used for detg. from 0.05 to 3.0 mg. Sb in Sn.; cf. *Snell, p. 253.* Recomm. (*I. C.*).

PYROGALLOL, in aq. soln. gives a white ppt. with Sb in dil. HCl contg. tartrate to give antimonyl tartrate ion. Procedure may be used for detn. of Sb and sepg. it from As; cf. Feigl, *Z. anal. Chem.* **64,** *41–47 (1924); C. A.* **18,** *3016; Prodinger, p. 115.*

9-METHYL-2,3,7-TRIHYDROXYFLUORONE, 0.5% soln. in ethyl alc. gives red ppt. with Sb (III); may be used as test tube or spot test. Test is sensitive and is apparently specific at pH 4.0 and in pres. of F ion. Wenger, Duckert, and Blancpain, *Helv. Chim. Acta* **20,** *1427–45 (1937); C. A.* **32,** *1205 (1938).* Prepn. of reagt.: triacetyl derivative made from *p*-quinone with acetic anhydride and H_2SO_4, and then it is mixed with acetaldehyde in ratio of 1 mol. of former to 1.2 of latter. The mixture is heated on water bath at 50°–60° for 1 hr. with 5 parts by wt. of ethyl alc. and one part of 5–10% H_2SO_4. Reagt. is pptd. by adding water. R. Duckert, *Helv. Chim. Acta* **20,** *362–7 (1937).*

ARSENIC

COCAINE-MOLYBDATE is prepared by mixing 1 part by vol. of 1% potassium molybdate soln., 2 parts of 0.1 *N* HCl, and 1 part of 2% cocaine soln. Pentavalent As in a soln. slightly acid with HCl gives a turbidity suitable for nephelometric detn. of amts. of As between 0.0005 and 0.06 mg. Phosphates must be absent and errors are small (2–3%). The method is said to be convenient and more exact than those

involving evolution of arsine; cf. *Yoe II, pp. 107–16.* **STRYCHNINE** may be used instead of cocaine; cf. *Snell, p. 241;* also **QUININE-ARSENOMOLYBDATE** may be used in a similar manner; cf. *Snell, p. 242; Yoe I, pp. 128–30.*

***N*-ETHYL-8-HYDROXYTETRAHYDROQUINOLINE HYDROCHLORIDE (KAIRIN),** 0.5% aq. soln. A drop of the test soln. is put on filter paper, allowed to dry, then moistened with HCl and a drop of the reagt. soln., a drop of $FeCl_3$ soln. is added and the spot is warmed. In the presence of as much as 6×10^{-7} mg. As (III) a reddish-brown coloration appears. Hg, Pb, and Cu must be absent; cf. W. Reppmann, *Z. anal. Chem.* **99,** *180–2 (1934).*

BARIUM

SODIUM RHODIZONATE, freshly prepd. 5% aq. soln. For spot test, place drop of neutral or sl. acid test soln. on filter paper and add drop of reagt. soln. A red to brown stain, becoming more red with dil. HCl, indicates Ba. Metals of H_2S and $(NH_4)_2S$ groups intfr. and should be removed before making test. Recomm. (*I. C.*). *Feigl, p. 137.* **TETRAHYDROXYQUINONE** gives a similar reaction and is considerably more stable than the rhodizonate; cf. under the heading *sulfate.*

BERYLLIUM

MORIN, 20 mg. in 100 ml. of acetone, is a valuable reagt. for detc. and detn. of minute amts. of Be. In 0.01 to 0.1 *N* NaOH soln. Be gives a yellow-green fluorescence visible in daylight or better in ultraviolet light. Estn. of minute amts. may be made by comparison with standards. Only Li, Ca, Zn, and Sc give fluorescence to intfr.; these may be masked or removed. Oxidizing agts. destroy reagt. and must be avoided. Recomm. (*I. C.*) E. B. Sandell, *Ind. Eng. Chem.*, (*Anal. Ed.*) **12,** *674, 762–4 (1940).*

1-AMINO-4-HYDROXYANTHRAQUINONE, 0.1% in alc., gives a red fluorescence with Be in alk. soln. This reagt. is said to be less sensitive but more nearly specific than morin. White and Lowe, *Ind. Eng. Chem.*, (*Anal. Ed.*) **13,** *809 (1941).*

QUINALIZARIN (1,2,5,8-TETRAHYDROXYANTHRAQUINONE), satd. alc. soln. or freshly prepared 0.05% soln. in 0.1 *N* NaOH. In alkaline soln. Be changes the color of the reagt. from reddish-violet to a distinct blue; it may be used as a test on spot plate as well as in other detc. methods; cf. *Feigl, p. 120.* A blank should be run along with the test. In solns. alkaline with NaOH, a moderate xs. of Al does not intfr.; Fe intfr. may be prevented by tartrate but the sensitivity is diminished by the latter. PO_4 should be absent. Mg gives the same color as Be; the latter, however, loses its color on addn. of bromine water while the Mg lake remains unaffected. The reagt. may be used for estn. of Be by adding xs. to unknown and titrating back to clear, pure, blue end point with standard Be soln.; cf. H. Fischer, *Z. anal. Chem.* **73,** *54–64 (1928).* As little as 0.1 mg. Be may be detd. After sepn. of Al, Be may be detd. colmtcly.; cf. *Snell, p. 399;* cf. also *C. A.* **30,** *2132 (1936),* and **31,** *3815 (1937).* Recomm. (*I. C.*) **ALKANNIN** or **NAPHTHAZARIN** may be used instead of quinalizarin although they are not as sensitive; cf. *C. A.* **30,** *5143 (1936).*

CURCUMIN, 0.1% alc. soln., forms an orange-red lake in faintly alkaline soln. contg. Be; the blank is yellow to brown in color. Pptn. occurs in concns. over 50 mg. Be per liter. For solns. contg. 0.05 to 1 mg. per liter, the reagt. may be used for colmtc. estn.; Fe and Al are removed before detn. by adding xs. NaF to sl. acid soln.; cf. Kolthoff, *J. Am. Chem. Soc.* **50,** *393–5 (1928); Snell, p. 398.* The addn. of starch glycerite increases sensitivity of colmtc. detn. W. E. Thrun, *Ind. Eng. Chem.*, (*Anal. Ed.*) **2,** *8 (1930).*

***p*-NITROBENZENEAZO-ORCINOL,** 0.025% soln. in dil. NaOH, is used for a spot test on filter paper giving an orange-red color. In testing, a drop of the reagt. is placed on the paper, then a little of the test soln. is applied to the middle of the spot, followed by another drop of reagt. In the presence of as much as 0.0002 mg. Be an

orange-red spot is obtained. Zn gives a similar color but the color disappears on the addn. of KCN soln.; Mg and Al are both inactive; cf. Komarowskii and Poluektov, *Mikrochemie* **14**, *315–7 (1934); Feigl, p. 121.* Recomm. (*I. C.*)

8-HYDROXYQUINOLINE (OXINE), in acetic acid soln., may be used to precipitate quantitatively Al, Fe, and Zn in acetic acid-amm. acetate soln. leaving Be unaffected which may be detd. by suitable means in the filtrate; cf. Lundell and Knowles, *Bur. Stand. J. Research* **3**, *91 (1929)*.

AURIN TRICARBOXYLIC ACID (ALUMINON), 0.1% aq. soln., gives a reaction similar to that with Al (q.v.); cf. Middleton, *J. Am. Chem. Soc.* **48**, *2125 (1926)*; Kolthoff, *J. Am. Chem. Soc.* **50**, *353–5 (1928)*.

BISMUTH

CINCHONINE POTASSIUM IODIDE reagt. is prepared by mixing 5 g. cinchonine with enough conc. HNO_3 to make a paste, dissolving the paste in water, diluting to about 50 ml., adding to 250 ml. KI soln. contg. 10 g. KI, diluting to 500 ml., allowing to stand 48 hrs., and then filtering. The reagt. is stable for long periods and any suspended matter which appears on standing should be filtered off before use. In a slightly acid soln. of Bi the reagt. gives an orange-red color or ppt. As a spot test, Bi may be recognized even in the presence of Cu, Pb, and Hg by different colors and a zoning effect when all are present. Cd does not intfr.; cf. *Feigl, p. 33.* The reagt. may be used for colmtc. detn. of 0.03 to 0.15 mg. Bi; cf. *Snell, p. 218.* **QUININE** with the iodide ion may be used instead of the cinchonine; cf. *Snell, p. 221, Yoe I, p. 133.* **GLYCEROL** has also been used with KI to keep the Bi colored compd. in suspension for colmtc. estn.; cf. P. Planes, *J. Soc. Chem. Ind.* **22**, *1259 (1903)*. **8-HYDROXYQUINOLINE (OXINE)** with KI is also suitable for detc. of as little as 0.5×10^{-6} mg. Bi and for colmtc. estn. of amounts up to 0.25 mg.; cf. *Snell, p. 221*, and *C. A.* **26**, *2391 (1932)*. Cinchonine recomm. (*I. C.*).

THIOUREA, solid or satd. aq. soln., gives a yellow color suitable for colmtc. detn. as well as for detc. Xs. reagt. is used to ppt. other metals from a test soln. strongly acid with HNO_3; cf. C. Mahr, *Z. anal. Chem.* **94**, *161–6 (1933); Snell, p. 220.* For use of thiourea in detn. of Bi in refined leads and tins, cf. *C. A.* **34**, *5778 (1940)*. Recomm. (*I. C.*).

PYROGALLOL, conc. aq. soln., will ppt. Bi quant. from a hot, slightly acid soln.; the yellow crystalline ppt., containing 62.84% Bi, may be washed, filtered off and dried for detn.; cf. Feigl, *Z. anal. Chem.* **65**, *448 (1925)*. The reagt. is also useful for sepg. Bi from Pb and Cu; cf. E. A. Ostroumov, *Zavodskaya Lab.* **4**, *1016–20 (1935); C. A.* **30**, *1684 (1936); Prodinger, p. 116.*

DIMERCAPTOTHIODIAZOLE and numerous similar compounds have been suggested for detc. and detn. of Bi; cf. J. V. Dubsky, A. Okac, B. Okac, and J. Trtilek, *Z. anal. Chem.* **98**, *184–93 (1934); ibid.*, **100**, *408–18 (1935)*, recomm. (*I. C.*); cf. also *Prodinger, p. 114* for use of **MERCAPTOBENZOTHIAZOLE.** 1% alc. soln. of **2-METHYL BENZOTHIAZOLE** with KI used for detc. of Bi in qual. scheme; B. Naiman, *J. Chem. Education* **14**, *484–6 (1937)*.

CUPFERRON (AMMONIUM NITROSOPHENYLHYDROXYLAMINE) has been used for the sepn. and detn. of Bi; cf. Pinkus and Dernier, *C. A.* **23**, *53 (1929); Prodinger, p. 79.*

DIPHENYLTHIOCARBAZONE (DITHIZONE), 25–50 mg. per liter of $CHCl_3$ or CCl_4 has been used for detc. and colmtc. detn. of minute amounts of Bi. The green color of the reagt. is changed to orange-red in the presence of Bi in a slightly alk. soln. Pb, Sn (II), Tl interference may be removed by making the soln. acid; cf. H. Fischer, *Z. angew. Chem.* **47**, *685–92 (1934)*; Willoughby, Wilkins and Kraemer, *Ind. Eng. Chem., (Anal. Ed.)* **7**, *285–6 (1935); A. O. A. C., p. 405.* For detn. of Bi in biological material, cf. D. M. Hubbard, *Ind. Eng. Chem., (Anal. Ed.)* **11**, *343 (1939)*.

CAFFEINE as sulfate or nitrate used to ppt. Bi which is subsequently detd. by a volmtc. method. Of the common ions only Ag, Cu, and Hg (I) intfr. Beale and Chandlee, *Ind. Eng. Chem., (Anal. Ed.)* **14**, *43 (1942)*.

ORGANIC REAGENTS FOR INORGANIC ANALYSIS

BORON, BORATE

TURMERIC paper and solution, **CURCUMIN** paper and solution. Turmeric soln. made by extraction of the powder with cold alc.; curcumin soln. 0.1% in alc. Papers made by immersion in solns. and drying. To test for a borate, the test paper is immersed in the sample acidified with HCl and then allowed to dry; a brownish-red color which is intensified on drying and which turns to a dark blue-green with NH_4OH indicates borate; cf. *U.S. Pharmacopoeia XI, p. 449; A. O. A. C., p. 459, 542.* Test papers are used for estn. of small amounts of B (under 0.1 mg. B_2O_3). B separated by volatilization as the methyl ester, absorbed in NaOH soln., evaporated, made acid, and tested with papers. Length of red stain permits estn. of boron; cf. *Snell, pp. 527–8; Yoe I, p. 134.* Solns. of turmeric or curcumin may be added to borate soln. or to residue after evaporation for colmtc. estn.; cf. *Snell, p. 526; Yoe I, p. 135.* Fe (III), Mo, Ti, Cb, Ta, Zr, give red colorations with these reagts. but differ in that NH_4OH does not cause the usual change in color. Oxidizing substances must be absent; phosphate and silicate ions diminish the sensitivity of the reaction; cf. *Feigl, p. 223.*

METHYL ALCOHOL.—In the absence of Cu, B may be easily detected and roughly estimated by adding the reagt. and H_2SO_4 (5 vol.: 1 vol.) and igniting the vapor contg. methyl borate to obtain a green bordered flame; cf. *U. S. Pharmacopoeia XI, p. 449;* W. Stahl, *Z. anal. Chem.* **101**, *342–56 (1935).*

MANNITOL or **GLYCEROL** can be used for the detn. of borate by titrating the test soln. to about pH 7, adding the reagent which makes the test soln. acid in proportion to the amount of borate present, and titrating back to neutrality with dil. standard NaOH; cf. *A. P. H. A., pp. 30–4; A. O. A. C., pp. 13, 460.*

***p*-NITROBENZENEAZOCHROMOTROPIC ACID (CHROMOTROPE 2B)**, 0.005% soln. in conc. H_2SO_4. As little as 8×10^{-5} mg. B may be detected by evaporating a drop of slightly alk. test soln. in a porcelain dish and adding 2 drops of the reagt. while the dish is still hot; on cooling, a violet to green color indicates B; cf. *Feigl, p. 225;* Komarowskii and Poluektov, *Mikrochemie* **14**, *317–20 (1934).* Recomm. (*I. C.*).

QUINALIZARIN (1,2,5,8-TETRAHYDROXYANTHRAQUINONE), 0.01% soln. in conc. H_2SO_4; other concentrations are better for colmtc. determinations; cf. literature reference. The violet color of the reagt. changes to blue in the presence of minute amounts of borate; cf. Feigl and Krumholz, *Mikrochemie, Pregl-Festschrift 77–86 (1929).* For detn. of B in soils and plants see Berger and Truog, *Ind. Eng. Chem., (Anal. Ed.)* **11**, *540–5 (1939).* For detn. of B in steel, cf. H. A. Kar, *Metals and Alloys* **9**, *175–7 (1938).*

TITAN YELLOW (CLAYTON YELLOW) in aq. soln. may be used to impregnate filter paper upon which sl. acid test soln. is dropped. In pres. of H_3BO_3 the spot is yellow and addn. of Na_2CO_3 or NH_4OH soln. turns it red. Mg, PO_4, and organic anions intfr. L. Robin, *Compt. rend.* **138**, *1046–8 (1904).* Recomm. (*I. C.*).

BROMINE, BROMIDE

FLUORESCEIN becomes eosin with change in color from greenish-yellow to pink by action of bromine liberated by suitable oxidizing agent. Test may be made on paper impregnated with reagt. and held over mouth of tube contg. unknown and oxidizing agent; *Feigl, p. 162.* Iodine giving similar reactions must be absent. For colmtc. detn. of bromide by fluorescein; cf. *Snell, p. 548.* **PHENOL RED**, 10 mg. per 100 ml. very dil. NaOH soln., reacts in a similar way but has several advantages. At pH 5.0 to 5.4 the color is changed from yellow to red or violet by 0.001 to 0.018 mg. Br. Iodide must be removed by boiling with $NaNO_2$ in acid soln.; cf. Stenger and Kolthoff, *J. Am. Chem. Soc.* **57**, *831–3 (1935).*

FUCHSIN-BISULFITE (SCHIFF'S REAGENT), 1% aq. soln. of fuchsin which has been decolorized with $NaHSO_3$ or SO_2. Bromine liberated by chromic acid soln. (25%) or chlorine produces a bluish color in the colorless reagt. Chlorides and iodides

do not interfere and the test may be used for detc. or colmtc. estn. of bromides in iodides and chlorides; cf. *Feigl, p. 163; Snell, pp. 544–5;* Recomm. (*I. C.*). Dilute H_2SO_4 may be used as a solvent for fuchsin and the colored substance formed from the bromine extracted with isoamyl alcohol for colmtc. estn.; cf. *Snell, p. 546.*

α-**NAPHTHOFLAVONE** (**7,8-BENZOFLAVONE; 2-PHENYL-1,4-α-NAPHTHOPYRONE**), 0.5% soln. in alc., is a reagt. which gives an intense rust-brown color with bromide ion in a neutral or acid soln. and may be used as an indicator in bromometric titrations; the color is reversibly discharged with As (III), Sb (III), Sn (II); cf. E. Schulek, *Z. anal. Chem.* **102,** *111–13 (1935);* cf. also *C. A.* **29,** *3934 (1935),* and *C. A.* **29,** *6523 (1935); Feigl, p. 164.* **DIPHENYLCARBAZIDE** may also be used as an indicator in titrating bromide solns. with 0.025 *N* mercuric nitrate soln.; H. R. McCleary, *Ind. Eng. Chem.,* (*Anal. Ed.*) **14,** *31 (1942).*

CADMIUM

β-**NAPHTHOQUINOLINE**, 3% soln. in 0.5 *N* H_2SO_4, is a reagt. which gives with KI a quant. ppt. of Cd as $(C_{13}H_9NH)_2CdI_4$ and may be used for detn. of Cd in Zn ores and in spelter; Group II metals do not hinder the detn.; cf. Berg and Wurm, *Ber.* **60,** *1664–71 (1927).* For less than 50 mg. of Zn a volmtc. method may be used; cf. Pass and Ward, *Analyst* **58,** *667–72 (1933).* Recomm. (*I. C.*).

DIPHENYLCARBAZIDE, satd. alc. soln., is used to impregnate paper used for a spot test. The test soln. is dropped on the paper which, after 1 or 2 minutes, is held over an open ammonia bottle to develop the blue-violet spot indicating Cd; by various means, interference by other Group II metals may be overcome; cf. *Feigl, p. 47.*

DINITRODIPHENYLCARBAZIDE, 0.1% alc. soln., gives with $Cd(OH)_2$ and other metallic hydroxides colored adsorption complexes; with KCN present, Cu does not intfr. with the Cd test which gives a greenish-blue color when test soln. is mixed on spot plate with NaOH, KCN and a little 40% formaldehyde; cf. *Feigl, p. 49.* Recomm. (*I. C.*).

DIPHENYLTHIOCARBAZONE (DITHIZONE), 30 mg. per liter of $CHCl_3$, may be used to detect minute amounts of Cd in a soln. made alk. with NaOH and contg. tartrate; the reagt. on shaking with the test soln. gives a red to violet color with Cd; Co and Ni give colorations under the same conditions; cf. H. Fischer, *Z. angew. Chem.* **47,** *685–92 (1934).* Recomm. (*I. C.*). For detn. of Cd in silicate rocks, cf. E. B. Sandell, *Ind. Eng. Chem.,* (*Anal. Ed.*) **11,** *364 (1939).*

NITROPHENOLARSINIC ACID, in 10% AcOH soln., is a specific qual. reagt. for Cd in AcOH soln.; 1 part of Cd in 200,000 parts of soln. will show a yellowish crystalline ppt. when warmed with the reagt.; cf. Pavelka and Kolmer, *Mikrochemie* **8,** *277–80 (1930).* Recomm. (*I. C.*).

HEXAMETHYLENETETRAMINE ALLYLIODIDE (ALLYL IODOUROTROPINE), 10% aq. soln., quantitatively ppts. a complex Cd compound, containing 11.45% Cd, which may be dried at 105° C. for gravmtc. detn.; cf. Evrard, *Ann. chim. anal. chim. appl.*, **11,** *322–6 (1929).* In the presence of Zn and some other metals the method is not satisfactory; cf. Hurd and Evans, *Ind. Eng. Chem.*, (*Anal. Ed.*) **5,** *16 (1933).*

1-(2-QUINOLYL)-4-ALLYL-THIOSEMICARBAZIDE, satd. soln. in 50% alc., with KI in a neutral or slightly acid soln. gives a yellow ppt. with Cd; Cu does not intfr.; cf. Scott and Adams, *J. Am. Chem. Soc.* **57,** *2541–2 (1935).*

8-HYDROXYQUINOLINE (OXINE) quant. ppts. Cd from an AcOH soln. buffered with AcONa; Cu is also pptd. The ppt. is $Cd(C_9H_6ON)_2 \cdot 1.5H_2O$; cf. Burg and Wurm, *Z anal. Chem.* **71,** *321 (1927);* or, $Cd(C_9H_6ON)_2 \cdot 2H_2O$; cf. Wenger, Cimerman and Wyszewianska, *Mikrochemie* **18,** *182 (1935).*

4-NITRONAPHTHALENE-DIAZOAMINOBENZENE-4-AZOBENZENE (CADION 2B), 0.02 g. in 100 ml. of ethyl alc. contg. 1 ml. of 2 *N* KOH, is said to be specific,—in absence of Hg,—as a spot test for Cd. A drop of reagt. is placed on filter

paper and a smaller drop of neutral or sl. acid (with AcOH) test soln. contg. tartrate is added. Finally a drop of 2 *N* KOH in 20% alc. is added. If as much as 0.002 mcg. Cd is present in the test drop, a pink spot surrounded by a blue circle will appear. F. P. Dwyer, *Australian Chem. Inst. J. & Proc.* **5**, *37–40 (1938); C. A.* **32**, *2871.*

CALCIUM

AMMONIUM OXALATE is the most commonly useful reagt. for detc. and detn. of Ca in soln. contg. in addn. to Ca only Mg and alkali metals and no strong acids. The detn. may be made by gravmtc. or volmtc. methods, the latter being done by titration of oxalic acid liberated from the ppt. by action of strong acid; cf. Hillebrand and Lundell, *Applied Inorganic Analysis (Wiley), pp. 493–503 (1929)* and other references. Recomm. (*I. C.*).

DIHYDROXYTARTARIC ACID OSAZONE (sodium salt) gives a yellow ppt. with Ca in even very low concn.; other alkaline earth metals behave similarly although Mg does not ppt. unless present in an amount greater than the Ca; alkali metals and ammonium do not intfr. Test is made by placing a small grain of the solid reagt. in depression of black spot plate and adding drop of neutral test soln.; the ppt. is formed slowly; cf. *Feigl, p. 140.* Recomm. (*I. C.*).

OLEIC, RICINOLEIC and **STEARIC ACIDS** are used in the estn. of Ca forming insoluble soaps which are determined by means of nephelometric or colorimetric measurements of the suspended soaps. In these methods it is usually necessary to make a preliminary sepn. of the Ca as CaC_2O_4 which is subsequently dissolved and detd. in the soln. freed from Mg and other interfering substances. The methods have been used in the detn. of Ca in urine, feces, blood, milk, and other organic materials. Samples used in the detn. should contain from 0.005 to 2.5 mg. Ca; cf. *Snell, pp. 449–53; Yoe I, pp. 143–7; Yoe II, pp. 119–25.* **SULFORICINOLEIC ACID** may be used in the same way and is said to have the advantage of not forming an insoluble Mg salt; for the method of use, cf. *Yoe II, 125–9; Snell, p. 453.*

ALIZARIN, 0.1% alc. soln., is used for the detn. of Ca which has been sepd. from Mg by pptn. as oxalate; the calcium oxalate is dissolved in dil. HCl, the reagt. and NH_4OH added, after several hours the blue-black crystalline ppt. of Ca alizarinate filtered off, washed, redissolved in oxalic acid, and the liberated alizarin estimated colmtcly.; 0.1 mg. Ca can be detd. to within 2 to 5%; cf. Laidlow and Payne, *Biochem. J.* **16**, *494–8 (1922); Yoe I, pp. 139–43; Snell, p. 465.*

PICROLONIC ACID, aq. soln., has been used for the microscopic detc. of Ca. which forms spiny, yellow balls or needles; Mg, K, Na, NH_4 ions do not intfr.; Cu and Pb intfr.; cf. J. Kisser, *Mikrochemie* **1**, *25 (1923).* The method has also been used for the colmtc. detn. of samples contg. between 0.02 and 0.15 mg. Ca; the Ca is pptd. as the picrolonate, filtered off, dissolved in hot water, xs. bromine water added, after warming a short time it is made alk. and the color compared with standards; cf. *Snell, p. 466.* In another method, Li picrolonate is used in xs. to ppt. the Ca salt and the xs. is detd. by titration with methylene blue; cf. A. Bollinger, *Australian J. Exptl. Med. Biol. Sci.* **13**, *75–8 (1935).* The Ca salt may also be used for direct gravmtc. detn. of Ca; cf. F. Alten and associates, *Biochem. Z.* **265**, *85 (1933);* Dvorzak and Reich-Rohrivig, *Z. anal. Chem.* **86**, *98 (1931).*

ANTIPYRINE may be used for an indirect colmtc. detn. of Ca which is quant. ppt. as $K_2CaNi(NO_2)_6$, the nitrite ion of which is estimated colmtcly. by use of antipyrine; Ba and Sr react similarly but Cu, Mn, Al, Fe, Zn, and Mg do not ppt.; the error should be less than 4%; cf. *Snell, pp. 462–3.*

HYDROQUINONE with sodium bisulfite, **1,2,4-AMINONAPHTHOLSULFONIC ACID,** and other organic reducing agents are used for an indirect colmtc. detn. of Ca. The calcium is obtained as the phosphate, amm. molybdate is added to form the phosphomolybdate which is then reduced to the "molybdenum blue" for colmtc. estn.; As must be absent; the method is suitable for detn. of 0.02 to 0.2 mg. Ca; cf. *Snell, pp. 454–6;* Roe and Kahn, *J. Biol. Chem.* **81**, *1–8 (1929).*

LORETIN (3-HYDROXY-7-IODOQUINOLINE-5-SULFONIC ACID) gives a bright orange-red ppt. with Ca salts in sl. acid solns. contg. between 5 ppm and 2% Ca. Mg, Na and K do not intfr. N. Schoorl, *Pharm. Weekblad* **76**, *620–5 (1939)*; *C. A.* **33**, *5767*.

CARBON DIOXIDE, CARBONATE, CARBON MONOXIDE

PHENOLPHTHALEIN-sodium carbonate, 2.5 ml. 0.5% phenolphthalein, 1 ml. 0.1 *N* Na_2CO_3, and 10 ml. water, is a reagt. which is colored red but becomes colorless by absorption of CO_2; a drop may be held on a coiled platinum wire to test a mixture of gases, or the gas evolved on acidulation of a solid or liquid unknown substance; the test is not specific as any acid-forming gas will decolorize the reagt.; cf. *Feigl, p. 221;* Feigl and Krumholz, *Mikrochemie* **8**, *131 (1930)*.

PHENOLSULFONEPHTHALEIN, BROMOTHYMOL BLUE and other indicators have been used for determining CO_2; cf. *Snell, pp. 117–24*.

HEMOGLOBIN with **PYROGALLIC** and **TANNIC ACIDS** has been used for the detn. of CO in blood and in gaseous mixtures; normal blood becomes gray when diluted with water and treated with tannic acid whereas in the presence of CO this color change does not occur and the color remains red; for details cf. Sayers, Yant and Jones, *Bur. Mines Repts. Investigations No. 2486 (1923)*; *Snell, pp. 112–5*.

CERIUM

GALLIC ACID, 0.02% aq. soln., gives a blue-violet color with ceric ion in a soln. contg. in addition amm. hydroxide and Na_2SO_4; for colmtc. detn. a sample contg. 0.03 to 0.07 mg. Ce should be used and the test soln. covered with a protective layer of mineral oil or ether; Th, La, Ti ions intfr.; Fe, Al, Cr, Mn, Co, Ni, and uranyl ions do not intfr.; **PYROGALLOL** may be used for detc. instead of gallic acid; cf. F. M. Shemyakin, *Zavodskaya Lab.* **3**, *1090–1 (1934)*; *C. A.* **29**, *2879*; *Snell, p. 366*. **TANNIN** may also be used; cf. *C. A.* **33**, *3289 (1939)*.

BENZIDINE, in AcOH soln., will detect 0.0002 mg. Ce when a drop of the test soln. is placed on filter paper, then one drop of dil. NaOH followed by a drop of the reagt.; Ce (III) or Ce (IV) give a blue coloration; the test is specific in the rare earth metals, but ions of Mn, Co, Cu, Ag, Tl, CrO_4 intfr. by reacting similarly; in the presence of these interfering metals the Ce may be pptd. with HF and then tested; cf. *Feigl, p. 132;* cf. also E. Herzfeld, *C. A.* **33**, *3289 (1939)*. The leuco base of **MALACHITE GREEN** is said to be slightly more sensitive to the Ce (IV) than is benzidine and the same ions intfr.; cf. L. M. Kul'berg, *J. Applied Chem. (U. S. S. R.)* **8**, *1452–6 (1935)*; *C. A.* **30**, *5143 (1936)*; **31**, *626 (1937)*.

CESIUM

DIPICRYLAMINE (HEXANITRODIPHENYLAMINE) in soln. in Na_2CO_3 gives ppt. with Cs but reaction is not distinctive; cf. van Nieuwenburg and van der Hoek, *Mikrochemie* **18**, *175–8 (1935)*; *C. A.* **30**, *43 (1936)*.

CHLORINE, CHLORIDE, CHLORATE, PERCHLORATE

***o*-TOLIDINE**, 1 g. per liter of 10% HCl (prepared by mixing the solid tolidine with HCl and then adding more water and HCl) is stable for 6 months; it gives a yellow coloration with water contg. 0.01 to 1.0 ppm chlorine and is used in detg. free or chloramine chlorine in water. Permanent standards may be made from $CuSO_4$ and $K_2Cr_2O_7$, or K_2CrO_4 and $K_2Cr_2O_7$; cf. Dragt and Mellon, *Ind. Eng. Chem.*, (*Anal. Ed.*) **10**, *256–8 (1938)*. The color is allowed to develop 5 to 15 minutes in the dark before comparison is made. More than 0.3 ppm Fe (III), 0.01 ppm Mn (III), 0.3 ppm nitrite and other oxidizing agents intfr. by producing the same coloration as chlorine; cf. *A. P. H. A., pp. 20–5; ibid., pp. 228–31*. The reagt. has also been used for estn. of free chlorine in sewage and in air; cf. *Snell, pp. 538–41; Yoe I, pp. 157–9*. Recomm. (*I. C.*).

BENZIDINE has also been recommended for colmtc. detn. of free chlorine giving a green color which is more intense and better suited for colmtc. comparison than is *o*-tolidine; the color fades in 2 or 3 minutes and sulfates intfr. if present in a concentration sufficient to ppt. benzidine sulfate; cf. Stratton, Ficklen and Hough, *Ind. Eng. Chem., (Anal. Ed.)* **4**, 2 *(1932)*; *Snell, p. 541.*

DIMETHYL-*p*-PHENYLENEDIAMINE gives a red coloration with free chlorine which is suitable for colmtc. estn.; cf. Kolthoff, *Chem. Weekblad* **23**, *203–4 (1926)*; *Snell, p. 542.*

CHLOROPHENOL RED or **BROMOCRESOL GREEN**, 0.1 g. in 100 ml. 20% alc. soln., are adsorption indicators for titration of *chloride* with standard $HgNO_3$; cf. Zombary and Pollak, *Z. anorg. allgem. Chem.* **215**, *255–6 (1933)*; cf. also *J. Am. Chem. Soc.* **56**, *1891 (1934)*. **DIPHENYLCARBAZIDE** is also recommended as an indicator for titration with $Hg(NO_3)_2$; cf. I. Roberts, *Ind. Eng. Chem., (Anal. Ed.)* **8**, *365–7 (1936)*. Diphenylcarbazide may also be used for detc. of chloride in a solid sample by volatilization therefrom of chromyl chloride the Cr of which affects the reagt. Recomm. *(I. C.)*. *Feigl, 160.* **DICHLOROFLUORESCEIN**, 0.1% soln. in 50% alc. contg. a small amount of NaOH, as an indicator in titration of chloride with Ag ion, has some advantages over unsubstituted fluorescein; cf. Fajans and Wolf, *Z. anorg. allgem. Chem.* **137**, *221 (1924)*; Kolthoff and associates, *J. Am. Chem. Soc.* **51**, *3273–7 (1929)*. **TARTRAZINE** has also been used; cf. Fearon and Gillespie, *Biochem. J.* **28**, *1629 (1934)*.

NITROBENZENE has been added to the soln. in the Volhard method to enable titration of xs. $AgNO_3$ without removal of AgCl; cf. Caldwell and Moyer, *Ind. Eng. Chem., (Anal. Ed.)* **7**, *38–9 (1935)*.

ANILINE HYDROCHLORIDE, in the absence of oxidizing agents, may be used for the detc. and colmtc. detn. of *chlorate*; reducing agents, other than the reagt., must be absent; cf. *Snell, p. 588; Yoe I, 163.* Chlorate may also be detc. by warming of unknown soln. with a mixture of 85% phosphoric acid and satd. manganous sulfate soln. On cooling, if chlorate is present, a violet color is obtained. Test can be made more sensitive by addn. of a drop of 1% alc. soln. of **DIPHENYLCARBAZIDE** which intensifies the color. Periodates and persulfates intrf. *Feigl, p. 190.* Recomm. *(I. C.)*.

NITROSODIMETHYLANILINE, 0.1% soln. in dil. alc., gives a violet color with *perchlorate* and is recommended for detc. and colmtc. estn. of this ion in Chile saltpeter; iodides must be removed with silver oxide; cf. *Yoe I, p. 163; Snell, p. 592.*

METHYLENE BLUE, 1.6% aq. soln., may be used for pptn. or colmtc. detn. of *perchlorate. Snell, p. 590.* Recomm. *(I. C.)*.

α-PHENYL-β-DIETHYLAMINOETHYL-*p*-NITROBENZOATE, 3 g. of the hydrochloride in 10 ml. water, may be used for detc. of *perchlorate* giving a turbidity or a white ppt. in neutral soln. with concns. of ClO_4 ion as low as 0.0025 *N*; nitrate ion also gives a ppt. in concns. of 0.01 *N*; iodide, oxalate, thiocyanate, and dichromate ions intfr.; cf. Marvel and du Vigneaud, *J. Am. Chem. Soc.* **46**, *2661–3 (1924)*.

CHROMIUM, CHROMATE

***s*-DIPHENYLCARBAZIDE**, satd. alc. soln., gives a violet coloration with chromate in a soln. acidified with AcOH; the color is suitable for estn. of Cr after oxidation to chromate by means of Na_2O_2 or other strong oxidizing agents; Fe does not intfr.; cf. A. Cazeneuve, *Analyst* **25**, *331 (1900)*. For the spot test, cf. *Feigl, pp. 98–102*; for colmtc. detn., cf. *Snell, p. 279* and *Yoe I, p. 166*; for application to qual. analysis scheme, cf. Stover, *J. Am. Chem. Soc.* **50**, *2363–6 (1928)*; for detn. of Cr in TiO_2, cf. Flatt and Vogt, *Bull. soc. chim.* (5) **2**, *1985–93 (1935)*. Recomm. *(I. C.)*.

DISODIUM-1,8-DIHYDROXYNAPHTHALENE-3,6-DISULFONATE (CHROMOTROPIC ACID), 1% aq. soln., gives a pink to light red color with chromate and may be used for colmtc. detn. of Cr in steel and in plant ash; the reaction is carried out in strongly acid soln. contg. H_3PO_4. Cr is oxidized and removed from most of the iron by treatment with NaOH and Na_2O_2; steel contg. less than

0.6% Cr may be analyzed advantageously with this reagt., and 0.02 mg. Cr may be detd. with an average error of 1%; vanadium does not intfr. if present in amounts less than Cr; cf. F. Garratt, *Ind. Eng. Chem.* 5, *298 (1913); Snell, p. 278; Yoe I, p. 165.* Recomm. (*I. C.*).

BENZIDINE, 0.1% in 10% AcOH may be used for detc. of Cr by oxidn. to chromate through use of Na_2O_2, placing drop on filter paper, then drop of reagt. to get a blue ring. Mn and V intfr. by giving similar color. Cf. *Feigl, p. 102.* Recomm. (*I. C.*).

SERICHROME BLUE R may be used for estn. of chromate by first dyeing wool yarn or flock with the reagt. which produces a crimson color. The dyed samples are changed to blues of varying intensities by immersion in chromic acid of varying concentrations; cf. G. C. Spencer, *Ind. Eng. Chem.*, (*Anal. Ed.*) 4, *245 (1932); Snell, p. 281.*

DIPHENYLAMINE or **DIPHENYLCARBAZIDE** may be used as an internal indicator in titrations with dichromate; cf. Kolthoff, *J. Am. Chem. Soc.* 53, *2902 (1931).*

ORCINOL (*s*-**DIHYDROXYTOLUENE**) in alc. soln. gives a brown coloration as a spot test on paper; cf. G. Gutzeit, *Helv. Chim. Acta* 12, *713 (1929).*

COBALT

α-NITROSO-β-NAPHTHOL, 7 g. in 100 ml. glacial AcOH, is used for detg. Co in tungsten steels by adding to a slightly acid soln. of the steel 6 ml. of reagt. for every 10 mg. of expected Co, filtering, washing and igniting to Co_3O_4; with comparatively large amounts of Co the oxide is reduced to the metal with hydrogen; the ppt. may be contaminated with Ni if this metal predominates in the original soln.; cf. *Standards and Specifications for Metals and Metal Products; Misc. Publication No. 120 of the Bu. of Standards, issued March 11th, 1933;* cf. also Hillebrand and Lundell, *Applied Inorganic Analysis, p. 326.* For colmtc. methods of detg. Co in paints and other commercial products cf. *Snell, pp. 322–4;* E. G. Jones, *Analyst* 43, *317 (1918);* in these methods the reagt. is dissolved in dil. NaOH; cf. also *Yoe 1, pp. 173–6.* As a spot test, giving a brown coloration, 0.05 mcg. Co may be detected; cf. *Feigl, pp. 83–6.* For detection and detn. of Co in soils cf. J. S. Hosking, *Australian Chem. Inst. J. and Proc.* 3, *172–83 (1936).* **β-NITROSO-α-NAPHTHOL** is said to be a more sensitive reagt. for Co; cf. I. Bellucci, *Gazz. Chim. Ital.* 49, *11, 294–8 (1919).* Yoe and Barton, *Ind. Eng. Chem.*, (*Anal. Ed.*) 12, *405–9 (1940)* discuss intfr. and colmtc. procedure using this reagt. Both reagts. recomm. (*I. C.*). **DINITROSORESORCINOL** has also been suggested for the gravmtc. detn. of Co, but results may be inaccurate; cf. Orndorf and Nichols, *J. Am. Chem. Soc.* 45, *1439 (1923);* Tomicek and Komarek, *Z. anal. Chem.* 91, 90 *(1932).* **NITROSO-R-SALT** (**α-NITROSO-β-NAPHTHOL-3,6-DISODIUM DISULFONATE**), in 0.5% aq. soln., is a useful reagt. for detc. of Co. in a soln. strongly acid with HNO_3; cf. van Klooster, *J. Am. Chem. Soc.* 43, *746 (1921).*

RUBEANIC ACID (**DITHIO-OXAMIDE**), 1% alc. soln., gives a brown ppt. with ammoniacal Co soln. and may also be used for a spot test; Cu gives a black ppt., and Ni gives blue under the same conditions; cf. *Feigl, p. 86.* **POTASSIUM DITHIO-OXALATE** has also been used; cf. Gutzeit, *Helv. Chim. Acta* 12, *(1929).*

FORMALDOXIME reagt. is made by boiling a mixture of 7 g. $NH_2OH \cdot HCl$, 15 ml. H_2O, and 3 g. trioxymethylene until clear, then cooling. For detc. of Co, add 1 drop reagt. and 2 drops of 10 *N* NaOH to 10 ml. of test soln. to get a pale yellow coloration or ppt. Mn (II), Ni, Fe (III) and Cu (II) intfr. Recomm. (*I. C.*). Cf. *C. A.* 27, *927 (1933).*

DIMETHYLGLOXIME, in the absence of Cu and Fe, may be used for detc. or colmtc. detn. of Co; Ni, if present, is filtered off for observation of the soln. which will be brown in the presence of as much as 0.5 mcg. per ml.; the error in the estn. may be as high as 10%; cf. *Snell, p. 327;* Braley and Hobart, *J. Am. Chem. Soc.* 43, *482 (1921).* The reaction is more sensitive if **BENZIDINE** or **TOLIDINE** is used along with the

dimethylglyoxime reagt.; cf. Spacu and Macarovici, *Bul. soc. Stiinte Cluj* **8**, *245–56 (1935); C. A.* **30**, *1684 (1936)*.

POTASSIUM XANTHATE gives a green ppt. with Co in a neutral or slightly acid soln.; Ni may ppt. but will dissolve in NH_4OH, making it possible to detect traces of Co in Ni; cf. Tougarinoff, *Ann. soc. sci. Bruxelles* **50B**, *168 and 235 (1930)*.

DIPHENYLTHIOCARBAZONE (DITHIZONE), in $CHCl_3$, has been used to detect traces of Co in Ni; cf. H. Fischer, *Wiss. Veroffentlich. Siemens-Konzern* **6**, *147–9 (1928); C. A.* **23**, *1364 (1929)*.

PHENYLTHIOHYDANTOIC ACID has been used for the sepn. and gravmtc. detn. of Co in the presence of Al, Cr, V, W, U, Mo, As, Ti, Zn, Mn, Ca and Mg. The Ni ppt. is washed out with NH_4OH and the violet colored ppt. is ignited and weighed as Co_3O_4; cf. Willard and Hall, *J. Am. Chem. Soc.* **44**, *2219; ibid.*, **44**, *2226; ibid.*, **44**, *2253 (1922)*.

THIOGLYCOLIC ACID ANILIDE, 2% alc. soln., is a reagt. for detc. of Co in a soln. from which Ag and the Cu-Sn groups have been removed. The test soln., made ammoniacal, is boiled, the reagt. added, boiled, and then made acid with HCl; a ppt. remaining on acidification indicates Co; cf. T. Berzin, *Z. anal. Chem.* **85**, *428–33 (1931)*.

ANTHRANILIC ACID (*o*-**AMINOBENZOIC ACID**) quant. ppts. Co from a soln. free from Zn, Cd, Ni, Mn, and Cu, and buffered to a pH of 4.4 or above; cf. Funk and Ditt, *Z. anal. Chem.* **93**, *241–7 (1933)*; H. Goto, *J. Chem. Soc. Japan*, **55**, *1156–63 (1934)*.

For a critical report on about 150 reagts. for detc. of Co see Wenger, Duckert, and Basset, *Helv. Chim. Acta* **24**, *657–70 (1941); C. A.* **35**, *6536 (1941)*.

COLUMBIUM

TANNIN with oxalic or tartaric acids has been used for the separation of Cb from Ta, and from Zr, Th, and Al; with Cb, tannin in the presence of oxalic acid gives a red ppt., whereas Ta gives a yellowish-brown; if Ta ppt. is contaminated with Cb, it is red. For details of quant. methods; cf. W. R. Schoeller, *The Analytical Chemistry of Tantalum and Niobium (1937)*, *Nordemann Publishing Co. (New York)*.

COPPER

α-BENZOINOXIME (CUPRON), 5% soln. in alc. gives a green ppt. with Cu from a hot ammoniacal soln. preferably free of NH_4 salts; tartrate prevents pptn. of Fe, Al, and other insol. hydroxides, thus permitting a sepn. of Cu from them; the ppt. may be dried at 100° C. for gravmtc. detn.; the reagt. may also be used for a spot test; cf. *Feigl. p. 38* and *Prodinger, pp. 63–66*. Recomm. (*I. C.*). For use in soil analysis, cf. J. S. Hosking, *Australian Chem. Inst. J. and Proc.* **3**, *172–83 (1936); C. A.* **30**, *6488 (1936)*; in steel analysis, Kar, *Ind. Eng. Chem.*, (*Anal. Ed.*) **17**, *193 (1935)*, and in amperometric titration of Cu, A. Langer, *Ind. Eng. Chem.*, (*Anal. Ed.*) **14**, *283 (1942)*.

SALICYLALDOXIME reagt. is prepared by dissolving 1 g. in 5 ml. alc., pouring into 95 ml. water at 80°, allowing to stand a few minutes and then filtering, or it may be made without isolation of the oxime by dissolving 2.22 g. of salicylaldehyde in 8 ml. ethyl alc., adding to a soln. of 1.27 g. of $NH_2OH \cdot HCl$ in 2 ml. H_2O, diluting with 15 ml. alc. then stirring slowly into 225 ml. H_2O at 80°. Asten and Riley, *J. Chem. Soc.* (**1933**) 314. It is more nearly specific than benzoinoxime and only Au and Pd, in addition to Cu, ppt. in a soln. acid with AcOH. The yellow-green ppt. of Cu $(C_7H_6O_2N)_2$ may be used as a spot test for detc. or gravmtc. detn., or for the sepn. of Cu from Cd, Ni, Pb, and other metals. Recomm. (*I. C.*) cf. F. Ephraim, *Ber.* **63**, *1928 (1930); ibid.*, **64**, *1210 (1931); Feigl. p. 40;* Ishibashi and Kishi, *J. Chem. Soc. Japan* **55**, *1060–9 (1934); C. A.* **29**, *702 (1936)*. For a nephelometric method using salicylaldoxime cf. Alten and associates, *Mikrochemie* **20**, *77 (1936)*. Cu may be sepd.

and quant. pptd. from Pb and Zn at pH 2.5 to 4.0; Biefeld and Ligett, *Ind. Eng. Chem., (Anal. Ed.)* **14**, *359–61 (1942)*. ***p*-HOMOSALICYLALDOXIME**, 1% aq. soln. with a little alc. is said to be easier to prepare than salicylaldoxime and is used in the same way; cf. Kao and Chen, *J. Chinese Chem. Soc.* **3**, *22–6 (1935)* *C. A.* **29**, *4691 (1935)*.

ANTHRANILIC ACID, 3% soln. of the sodium salt, gives a greenish crystalline ppt. $Cu(C_7H_6O_2N)_2$, which is formed in neutral or acidic (AcOH-AcONa) soln., and has been used for gravmtc. and volmtc. detn.; at pH 2.8 to 3.0 no other metals ppt.; cf. Funk and Ditt, *Z. anal. Chem.* **93**, *345–7 (1933)*; H. Goto, *J. Chem. Soc. Japan* **55**, *1156–63 (1934)*; *C. A.* **29**, *1029 (1935)*; *Prodinger, p. 37.*

α-QUINALDINIC ACID, about 5% soln. of the sodium salt, has been used for the gravmtc. detn. and for separation of Cu from Cd, P, As, Pb, Ni, Co, and Mn; a green ppt. is formed in sl. acid soln. (H_2SO_4) and is dried at 125° C. to Cu $(C_{10}H_6NO_2)_2 \cdot H_2O$; Zn and uranyl also ppt.; cf. Ray and Bose, *Z. anal. Chem.* **95**, *400–14 (1933)*; Lindsey and Shennan, *Analyst* **65**, *636 (1940)*; *C. A.* **35**, *1340*; *Prodinger, p. 55.*

POTASSIUM ETHYL XANTHATE, 0.1% aq. soln. prepared fresh every day, is used for the colmtc. detn. of Cu in amounts less than 1 mg. and gives a yellow color in neutral or acid soln.; there is an error of 10–15% in detns. of 0.005 to 0.018 mg. of Cu; Fe, Pb, Ni, Co, Zn, and Mn in small amounts are said to be without interference but in plant ash it is best to separate out Cu first as CuS; *A. O. A. C., p. 130; Snell, pp. 152–5; Yoe I, p. 184.*

SODIUM DIETHYLDITHIOCARBAMATE, 0.1% aq. soln. is stable for several weeks if kept in a brown bottle and may be used for detc. of Cu in dilutions as low as 0.01 ppm and for colmtc. estn. of low concentrations as found in water which has been treated with $CuSO_4$ as an algaecide. The sample for detn. should not contain over 0.1 mg.; concentrations between 0.1 and 1.0 ppm are best for estn.; in this concentration a brown coloration is obtained and at higher concentrations a brown ppt. is formed; the reaction should be carried out in a slightly ammoniacal soln.; other metals in comparable amounts are not likely to intfr. although cyanide must be absent; cf. *A. P. H. A., pp. 25–6*; Callan and Henderson, *Analyst* **54**, *650 (1929)*. For a more general discussion cf. *Snell, pp. 164–6*; for Cu in milk cf. Conn and others, *Ind. Eng. Chem., (Anal. Ed.)* **7**, *15–23 (1935)*; for Cu in blood and other biological materials cf. S. L. Tompsett, *Biochem. J.* **29**, *480–6 (1915)*.

THIOGLYCOLIC β-AMINONAPHTHALIDE (THIONALID), alc. or AcOH soln. freshly prepared, ppts. Cu as a yellow compound from acid soln.; most of the metals which are pptd. by H_2S are likewise pptd.; in the absence of intfr. metals, the reagt. may be used for gravmtc., volmtc., colmtc., or nephelometric detn.; cf. Berg and Roebling, *Z. angew. Chem.* **48**, *430–2* and *597–601 (1935)*. It is claimed that Cu can be quant. sepd. from Tl, Fe, Ca, Ba, Mg, Zn, Cd, Mn, Co, Ni, Cr, Pb and Al; cf. *Prodinger, p. 88.*

RUBEANIC ACID (DITHIO-OXAMIDE), 0.5% alc. soln., gives a dark green to black ppt. with Cu, and as a spot test may be used for detc. of Cu in the presence of a large excess of Co, Ni, Fe, and Cd; cf. Ray, *Z. anal. Chem.* **79**, *94 (1930)*; *Feigl, pp. 44–46.* Recomm. (*I. C.*).

MERCAPTOBENZOTHIAZOLE, alc. soln., gives a yellow ppt. with Cu and also forms ppts. with Au, Ag, Pb, and Hg but not with Ni, Co, Zn, Cd, Mg, Mn, Ca, Ba, and Sr; cf. Spacu and Kuras, *Z. anal. Chem.* **102**, *24* and *108 (1935)*. **DIMERCAPTOTHIODIAZOLE** is similar in its actions with metals; cf. Ray and Gupta, *J. Ind. Chem. Soc.* **12**, *308–17 (1935)*; *C. A.* **29**, *7214 (1935)*; *Prodinger, p. 112.*

DIPHENYLTHIOCARBAZONE (DITHIZONE), in $CHCl_3$ or CCl_4 soln., can be used for the colmtc. detc. and detn. of mcg. quantities of Cu; cf. Fischer and Leopoldi, *Z. angew. Chem.* **47**, *90–2 (1934)*; R. M. Mehurin, *J. Assoc. Official Agr. Chem.* **18**, *192–4 (1935)*; *Feigl, p. 46.* For review of uses of this reagt., cf. Wichmann, *Ind. Eng. Chem., (Anal. Ed.)* **11**, *66–72 (1939)*.

PYRIDINE and thiocyanate may be used for pptn. of Cu as $Cu(CSN)_2 \cdot 2C_5H_5N$ which is dissolved in $CHCl_3$ for colmtc. detn.; or xs. KCNS may be titrated for volmtc.

detn.; cf. *Snell, pp. 159–62;* Hawk and Bergheim, *Practical Physiological Chemistry, 10th Ed., p. 468;* Tettamanzi, *Industria Chimica* **9**, *609–10 (1934); C. A.* **28**, *6653.* **BENZIDINE** or **TOLIDINE** may be used instead of pyridine; cf. *Z. anal. Chem.* **67**, *31 (1925).* Benzidine may be used with sodium salicylate for a rough colmtc. estn. of Cu; cf. *Snell, p. 162;* for other reactions of benzidine used in the detc. and detn. of Cu cf. *C. A.* **30**, *43 (1936);* **29**, *4498 (1935);* **29**, *6167 (1935);* **28**, *1951 (1934).*

The **AMMONIUM** salt of **NITROSOPHENYLHYDROXYLAMINE (CUPFERRON)**, 6% aq. soln. is a reagt. which is stable for weeks and gives a ppt. of Cu, in a neutral or slightly acid (AcOH) soln., which may be ignited to CuO for gravmtc. detn.; many other metals, such as Pb, Bi, Ag, Hg, Sn, and Fe, intfr. by pptg. also; Baudisch and King, *Ind. Eng. Chem.* **3**, *629 (1911);* cf. also *C. A.* **29**, *3624 (1935); Prodinger, p. 72–75.*

5,7-DIBROMO-8-HYDROXYQUINOLINE, 0.5% soln. in 5 *N* HCl or satd. soln. (about 0.3%) in acetone, may be used for the gravmtc. detn. of Cu in micro quantities as in water; the ppt. is $C_{18}H_5O_2N_2Br_4Cu$; cf. Berg, *Z. anal. Chem.* **70**, *347 (1927);* L. W. Haase, *Z. anal. Chem.* **78**, *113–24 (1929);* cf. also *Mikrochemie* **17**, *127 (1935)* and *C. A.* **30**, *983 (1936).* Unsubstituted **8-HYDROXYQUINOLINE (OXINE)** may also be used; in AcOH soln., Cu may be detd. in presence of Be, Mg, Ca, Cd, Pb, As and Mn, cf. *Prodinger, p. 110.*

BENZOTRIAZOLE in 2% aq. soln. gives quant. pptn. of Cu as a blue-green compd., $(C_6H_4N_3)_2Cu$, at pH 7.0–8.5. Ni, Co, Ag, Cd, Zn intfr. J. A. Curtis, *Ind. Eng. Chem., (Anal. Ed.)* **13**, *349–51 (1941).*

CYANIDE

BENZIDINE, in AcOH soln., is oxidized to a blue compound by nascent oxygen from interaction of $Cu(OAc)_2$ and HCN; in the absence of other oxidizing and reducing agents, the reaction is specific for HCN. Paper may be impregnated with the reagt. and $Cu(OAc)_2$ solns. and, while moist. exposed to the gas suspected of contg. HCN; a distinct blue coloration indicates HCN; solids or solns. may be tested by acidification to liberate HCN. With controlled conditions, the test may be made roughly quant.; cf. *Feigl, p. 176.* Sieverts and Hermsdorf, *Z. angew. Chem.* **34**, *3 (1921);* cf. also *C. A.* **7**, *3292.* **PHENOLPHTHALIN** will detect 0.2 ppm HCN which in the presence of dil. copper soln. yields the red phenolphthalein; Childs and Ball, *Analyst* **60**, *294–9 (1935).*

PICRIC ACID, alkaline soln., is a reagt. for impregnating paper and gives a red to brown spot with cyanide of low concn.; sulfide gives a similar color; cf. G. Gutzeit, *Helv. Chim. Acta* **12**, *713 (1929);* R. G. Smith, *J. Am. Chem. Soc.* **51**, *1171 (1929).*

FLUORIDE

SODIUM ALIZARINSULFONATE (ALIZARIN S) as a 0.05% aq. soln. is much used as an indicator in titration of fluoride solns. with standard thorium nitrate (0.05 to 1.0 *N*). The fluoride soln. should be adjusted to pH 3.0–3.2. The end point is shown by formation of pink color of thorium alizarin lake. Phosphate and certain other ions intfr. and are frequently eliminated from sample by distn. of the fluorine from sulfuric and perchloric acids. For detn. of F in soils cf. *A. O. A. C. p. 13;* in insecticides, *ibid. p. 51,* and in water, *same reference, p. 529.* In analysis for F in waters, however, distillation is usually unnecessary and detn. is made by colmtc. methods involving the use of the **ZIRCONIUM-ALIZARIN** lake which is changed from red-violet to yellow by an xs. of fluoride; the extent of the decoloration is a measure of amount of F. For details of detg. 0.1 ppm of F in presence of 500 ppm SO_4 cf. Lamar and Seegmiller, *Ind. Eng. Chem., (Anal. Ed.)* **13**, *901 (1941).* See also report of American Water Works Association Committee on methods of detg. fluorides, *J. Am. Water Works Assoc.* **33**, *1965–2017 (1941).* The color change of the Zr lake may be used as a spot test for F, *Feigl, p. 170.* Recomm. *(I. C.).*

***p*-DIMETHYLAMINOAZOPHENYLARSONIC ACID** gives a brown insol. compound with zirconium salts which turns red with F ion due to liberation of the

free dye; as with the alizarin reagt., other ions which remove Zr or form complexes with F intfr.; in all cases of intfr. the F may be separated out as HF or SiF_4; cf. *Feigl, p. 172.* Recomm. (*I. C.*).

After conversion to H_2SiF_6 and the treatment with ammonium molybdate, fluorine may be detc. by the oxidation of **BENZIDINE** to a blue compd. and simultaneous reduction of Mo to molybdenum blue; phosphates, arsenates, and silicates react similarly; cf. *Feigl, p. 173.* Cf. also Pertusi, *C. A.* **25,** *2076 (1931).* Recomm. (*I. C.*).

TRIPHENYLTIN CHLORIDE has been suggested as a reagt. for the gravmtc. detn. of fluoride which ppts. as $(C_6H_5)_3$ SnF. Allen and Furman, *J. Am. Chem. Soc.* **54,** *4625–31 (1932).*

GALLIUM

QUINALIZARIN, 0.01% alc. soln., will detect and determine colorimetrically Ga in concns. from 0.02 mg. to 0.2 mg. per liter by formation of a pink to amethyst colored lake. The test soln. should be normal in NH_4OAc, 0.5 *N* in NH_4Cl, have a pH of about 5 and should contain 0.5 g. NaF per liter. Ga may be separated from most metals but the test sample should not contain more than 10 mg. Al or more than 1 mg. Fe; V and Mo must be absent; cf. Willard and Fogg, *J. Am. Chem. Soc.* **59,** *40–5 (1937).* Recomm. (*I. C.*).

MORIN, satd. soln. in methyl alc., gives a green fluorescence in a soln. slightly acid with AcOH; Al gives the same test but its fluorescence is prevented by NaF; the Ga is also affected by the NaF but not as much as the Al; cf. G. Beck, *Mikrochemie* **20,** *194–7 (1936).* Recomm. (*I. C.*).

8-HYDROXYQUINOLINE (OXINE), 0.1% in dil. AcOH, may be used to detect minute amts. of Ga. Test soln. at pH 2.6–3.0 is shaken with reagt. and $CHCl_3$. Chloroform layer shows yellowish fluorescence in ultraviolet light if Ga is present. Fe (III), Cu (II), vanadate, and molybdate must be removed; other elements do not intfr. E. B. Sandell, *Ind. Eng. Chem.*, (*Anal. Ed.*) **13,** *844 (1941).*

GERMANIUM

BENZIDINE, 0.1% soln. in AcOH, may be used for a spot test; to a drop of the test soln. on a filter paper, is added a drop of amm. molybdate soln., a drop of HNO_3, then a drop of reagt., and the color developed with NH_3 fumes; as little as 0.25 mcg. of Ge gives a blue spot; the same reaction is given by Si, As, P_2O_5 and these must be absent; cf. Komarovskii and Poluektov, *Mikrochemie* **18,** *66–73 (1935).* Recomm. (*I. C.*).

Germanic acid, H_2GeO_3, reacts towards reagts. listed under *boron* in a manner similar to that of boric acid; **QUINALIZARIN** is especially recommended; cf. N. S. Poluektov, *Mikrochemie* **18,** *48–9 (1935).*

GOLD

Reducing agents such as *m*-**PHENYLENEDIAMINE, FORMALDEHYDE, PHENYLHYDRAZINE, BENZIDINE,** or **ACETYLENE** may be used for reduction of gold ion to colloidal gold which can be detc. or determined colmtcly.; cf. *Snell, pp. 402–8.* **BENZIDINE** may be used in a spot test with Au (III) giving the familiar blue spot; many other ions react similarly; cf. Malatesta and Di Nola, *Bull. Chim. Farm.* **52,** *461 (1912); Feigl, p. 71.* For analysis of Au and sepn. from the platinum metals, cf. F. E. Beamish, et al., *Ind. Eng. Chem.*, (*Anal. Ed.*) **9,** *174–6 (1937).*

DIMETHYLAMINOBENZALRHODANINE, satd. alc. soln., is used to impregnate paper for a spot test; Au in neutral or slightly acid soln. gives a reddish-violet ppt. or spot; Ag, Hg, and Pd react in a similar manner; *Feigl, p. 71;* cf. also *C. A.* **25,** *2380 (1931).*

PYRIDINE, 1 vol. in 9 vol. 40% HBr, gives orange to maroon colored crystals with Au (III) in an acid soln. if the concn. of Au is above 0.01%; cf. M. N. Short, *Microscopic Determination of the Ore Minerals, Bull. 825 U. S. Geol. Survey, Pt. 4 Microchemical Methods (1931).*

HYDROGEN ION

See table on **ACID-BASE INDICATORS.**

INDIUM

MORIN as satd. soln. in alc. is said to give a distinctive green fluorescence with In in presence of dil. mineral acid. It may be recognized even in admixture with Al, Sc, and Ga; cf. G. Beck, *Mikrochim. Acta* **2,** *287–90 (1937); C. A.* **32,** *1606.*

A sensitive spot test for In may be made by the use of **ALIZARIN-** impregnated paper to which is added a drop of the prepared test soln. and which is then dipped in a satd. aq. soln. of H_3BO_3 to get a red spot if In is present; most elements of the $(NH_4)_2S$ group intfr., cf. Komarovskii and Poluektov, *Mikrochemie* **16,** *227–32 (1934).*

In may be detd. with **8-HYDROXYQUINOLINE** by pptn. from buffered AcOH soln. Cf. Geilmann and Wrigge, *Z. anorg. allgem. Chem.* **209,** *129 (1932).*

IODINE, IODIDE

The familiar **STARCH** test for free iodine has been used with some success for the colmtc. estn. of iodine; cf. *Snell, p. 569.*

***o*-TOLIDINE,** 0.6% soln. in alc., gives with iodine a blue-green color suitable for colmtc. detn. of amounts between 0.01 mg. and 0.10 mg.; iodides may be oxidized to free iodine with H_2O_2 an xs. of which does not intfr.; iodates may be reduced for detn.; the test is made in a neutral soln.; nitrites are oxidized with H_2O_2 and bicarbonate decomposed by boiling; under conditions of the test 1500 ppm of chloride or bromide have no effect; Fe, Cu, Hg, and other metals must be removed if present in a concn. high enough to cause pptn. with the reagt.; cf. Lange and Ward, *J. Am. Chem. Soc.* **47,** *1000–3 (1925).*

METHYLENE BLUE soln. is decolorized by sulfite in a soln. 2 *N* with HCl at an immeasurably slow rate in the absence of iodide; up to 4 mcg. iodide may be detd. with errors no greater than 5% by observing the rate of fading of the reagt. in the presence of iodide as catalyst; cf. H. P. Lundgren, *J. Am. Chem. Soc.* **59,** *413–6 (1937).*

DIPHENYLCARBAZIDE as a satd. soln. in alc. may be used as an indicator in titration of iodide by means of $Hg(NO_3)_2$ soln. The end point is rendered very distinct by the presence of 10 to 15% of purified dioxane; cf. H. R. McCleary, *Ind. Eng. Chem., (Anal. Ed.)* **14,** *31 (1942).*

DIOXANE (DIETHYLENE OXIDE) commonly contains peroxides which oxidize iodide to iodine which colors the soln. and permits detc. and colmtc. detn. of small amts. of I as in iodized salt. Saifer and Hughes, *J. Biol. Chem.* **118,** *241–5 (1937); ibid.* **121,** *801 (1937).*

IRIDIUM

MALACHITE GREEN, LEUCO BASE, 1% soln. in glacial AcOH, is oxidized to the green color by $(IrCl_6)^{--}$ in an acid soln. The test is given by Ir in dilutions of 0.14 ppm in water; 1 part Ir in the presence of 3,000 parts of Pt may be detected. The reaction is not affected by moderate amounts of Rh, Os, and divalent Pd; free Cl, Au (III), and $(PdCl_6)^{--}$ must be removed; cf. L. A. Chugaev, *Ann. inst. platine No. 7, 205–7 (1929); C. A.* **24,** *2689 (1930).* Recomm. (*l. c.*).

BENZIDINE has been used for the detc. of Ir in the presence of Pt and for its approximate detn.; a deep blue color is given by tetravalent iridium; other oxidiz-

ing agents must be absent; cf. V. G. Khlopin, *Ann. inst. platine* **1**, *324–30 (1926); Snell, p. 425.*

IRON

α,α'-DIPYRIDYL, 1–2% soln. in alc. or dil. HCl, has had much usage in detc. and detn. of Fe (II) ion. The test is carried out in slightly acid soln. and gives an intense, stable, red coloration; in dil. soln. and in the absence of Cu (I) the reaction is specific; cf. F. Blau, *Ber.* **21**, *1077 (1888); Snell, pp. 310–11; Feigl, p. 96; C. A.* **35**, *2439 (1941).* For detn. of Fe in soil, cf. Dyer and McFarlane, *Can. J. Research 16B No. 3, 91–6 (1938), C. A.* **32**, *4263;* in biological materials, cf. S. H. Jackson, *Ind. Eng. Chem., (Anal. Ed.)* **10**, *302–4 (1938).* This reagt. has also been used for detn. of Fe in cereal products; Andrews and Felt, *Cereal Chem.* **18**, *819–26 (1941), C. A.* **36**, *1393.* Reagt. recomm. *(I. C.).*

o-PHENANTHROLINE is similar to α,α'-dipyridyl in regard to reaction with Fe (II). Saywell and Cunningham have used it for detn. of Fe in fruit juices, *Ind. Eng. Chem., (Anal. Ed.)* **9**, *67–9 (1937).* Hummel and Willard report no intfr. from pyrophosphate, Pb, Zn, Al, Hg, As, F, I; *ibid.* **10**, *13–15 (1938);* cf. also Fortune and Mellon, *ibid.* **10**, *60.*

DIMETHYLGLYOXIME, 1% alc. soln., gives with Fe (II) in ammoniacal soln. a red, soluble compound useful for detc. and detn. with errors of 1 to 2% in detn. on concns. of 10 to 50 ppm; Ni intfr. is prevented by addn. of KCN; Cu and Co should be absent as well as large amounts of Al and Zn; Fe (III) is kept in soln. by the use of tartrate; cf. *Snell, p. 308; Yoe I, pp. 248–9; Feigl, p. 98.* Recomm. *(I. C.).*

7-IODO-8-HYDROXYQUINOLINE-5-SULFONIC ACID (FERRON) has been found satisfactory for detn. of Fe (III). The test soln. should be acidified to pH of about 3; the reagt., in a satd. aq. soln., gives a green, stable color with Fe (III); at concns. as low as 0.1 ppm the color is perceptibly different from the yellow of the reagt. soln.; fluoride ion prevents color development but otherwise the reagt. is unaffected by any other ion in concn. comparable to that of Fe (III); cf. J. H. Yoe, *J. Am. Chem. Soc.* **54**, *4139–43 (1932);* Yoe and Hall, *ibid.* **59**, *872 (1937);* Clark and Sieling, *Ind. Eng. Chem., (Anal. Ed.)* **8**, *256–7 (1936); Snell, p. 302.* Recomm. *(I. C.).*

THIOGLYCOLIC ACID (MERCAPTOACETIC ACID), 4 ml. dissolved in 8 ml. conc. NH_4OH in 50 ml. of water, gives with Fe (III), at a pH of 8.0 to 10.0, a blue to purple coloration which may be used for estn. of Fe in milk, blood or other materials. With Fe (II) a reddish color is given. The color may fade but is restored on shaking in air. The color is given in concns. of 0.1 ppm and the errors are no larger than 2%. The reagt. soln. should be made as needed; cf. *Snell, p. 298* for details and bibliography. Swank and Mellon found this reagt. to be superior to many others in regard to freedom from intfr. by many anions which are usually troublesome, e.g. phosphate, fluoride, tartrate; cf. *Ind. Eng. Chem., (Anal. Ed.)* **10**, *7–9 (1938).*

SALICYLIC ACID, 10% aq. soln. of the sodium salt, is a reagt. which gives an amethyst color with Fe (III) ion but no color with Fe (II) ion; strong acids decompose the colored compound and sunlight causes fairly rapid fading; phosphate, fluoride, and ions which form complexes with Fe (III) intfr. in detc. and detn. The test is made in a soln. slightly acid with AcOH and the sample should contain less than 0.2 mg. Fe (III); cf. J. P. Mehlig, *Ind. Eng. Chem., (Anal. Ed.)* **10**, *136–9 (1938)* and *Yoe I, pp. 243–5; Snell, p. 301.* Recomm. *(I.C.).* **SALICYLSULFONIC ACID** has been used for detn. of minute amounts of Fe in sputum; cf. *Snell, p. 302.* **THIOSALICYLIC ACID,** which gives a yellow coloration with minute amounts of Fe in ammoniacal soln., has been used for Fe detn. on 0.1 ml. of blood; cf. *Snell, p. 300;* cf. also *C. A.* **32**, *1207 (1938).*

CUPFERRON (AMMONIUM SALT OF NITROSOPHENYLHYDROXYLAMINE), 6% aq. soln., is widely used for sepg. iron (also V, Zr, Ti, Sn, Cb, Ta) from other elements such as Al, Be, P, Mn, Ni, and hexivalent U. The pptn. is carried out in an acid soln. and the pptd. Cu may be dissolved out of the ppt. with NH_4OH: cf. O. Baudisch, *Chem. Ztg.* **33**, *1298 (1909);* Baudisch and King, *Ind. Eng. Chem.* **3**, *629*

(1911); E. Benedetti, *Rev. facultad cienc. quim. (Univ. La Plata)* **9**, *59–68 (1934)*, *C. A.* **29**, *3624 (1935)*; cf. also Hillebrand and Lundell, *Applied Inorganic Analysis*, *pp. 109–14 (1929)*.

p-n-**BUTYLPHENYLARSONIC ACID**, 0.75% aq. soln., is useful as a precipitant for detg. or sepg. Fe; most of the metals commonly associated with Fe do not intfr., although Zr, Sn, Ti, Th, UO_2, Ce, and the anions of F, PO_4, tartrate, and citrate should be absent; pptn. is from a soln. approximately 0.4 *N* in a mineral acid and at a temperature of 80–90° C.; cf. Craig and Chandlee, *J. Am. Chem. Soc.* **56**, *1278–9 (1934)*.

In volmtc. methods of iron detn., titration of Fe (II) with oxidizing solns. may be made convenient by the use of internal indicators such as **DIPHENYLAMINE SULFONIC ACID**; cf. Sarver and Kolthoff, *J. Am. Chem. Soc.* **53**, *2902–6 (1931)*; **o-PHENANTHROLINE**; cf. Walden, Hammett, and Chapman, *J. Am. Chem. Soc.* **55**, *2649 (1933)*; **α,α'-DIPYRIDYL**; cf. Nieuwenburg and Blumendal, *Mikrochemie* **18**, *39 (1935)*; and **PHENYLANTHRANILIC ACID** (**o-DIPHENYLAMINE CARBOXYLIC ACID**); cf. Suirokomskii and Stepin, *J. Am. Chem. Soc.* **58**, *928–9 (1936)*.

DIISONITROSOACETONE, 1% aq. soln., gives an intensely blue color with Fe (II) even in very dil. solns.; Co and Ni intfr.; xs. Mn reduces sensitivity; cf. Dubsky and Kuras, *Chem. Listy* **23**, *496 (1929)*; *C. A.* **24**, *801 (1930)*. Recomm. (*I. C.*).

ACETYLACETONE, 0.5% freshly prepared alc. or aq. soln., gives with as little as 3 mcg. of Fe a distinctly red soln. which may be used for estn. of Fe; the sample should contain between 3 and 60 mcg. Fe; the color is stable for weeks and the reagt. may be used wherever thiocyanate is applicable; the test is made in slightly acid soln.; cf. A. Combes, *Compt. rend.* **105**, *868 (1887)*; H. V. Pulsifer, *J. Am. Chem. Soc.* **26**, *967 (1904)*; cf. also *Snell, p. 303* and *Yoe I, pp. 245–8*.

DINITROSORESORCINOL, aq. soln., gives green colors or ppts. with Fe (II) and Fe (III) in neutral soln.; Co and Cu also react; cf. Nichols and Cooper, *J. Am. Chem. Soc.* **47**, *1268 (1925)*; for use of this reagt. as a specific stain for iron in tissues, cf. A. A. Humphrey, *Arch. Path.* **20**, *256–8 (1935)*, *C. A.* **29**, *8035 (1935)*.

LANTHANUM

8-HYDROXYQUINOLINE (OXINE) when added to a dil. AcOH soln. contg. La ppts. $La(C_9H_6ON)_3$ upon addition of NH_3; the ppt. may be dried for gravmtc. detn. or dissolved for titration with $KBrO_3$-KBr; cf. Th. I. Pirtea, *Z. anal. Chem.* **107**, *191–3 (1936)*.

LEAD

DIPHENYLTHIOCARBAZONE (DITHIZONE), 1 to 10 mg. dissolved in 100 ml. CCl_4 or $CHCl_3$, is a soln. which may be preserved for 4 to 8 weeks when care is taken to prevent contamination, oxidation, and long exposure to sunlight. The reagt. is widely used for detc., sepn., colmtc. and titrimetc. detn. of minute amounts of Pb; in soln. contg. KCN, NH_3, and citric acid at pH of about 9.5, Pb leaves the aq. phase to form a chloroform-soluble, red, dithizonate; other metals, except Sn (II), Bi, and Tl, do not intfr. unless present in great xs.; cf. *A. O. A. C., pp. 394–409*; *A. P. H. A., pp. 241–5*; *Snell, pp. 202–4*; *Feigl, p. 31*. For survey of use of dithizone in analysis for Pb and other metals, cf. *Prodinger, pp. 117–141*. For Pb in sugar products, cf. T. D. Gray, *Ind. Eng. Chem.*, (*Anal. Ed.*) **14**, *110–4 (1942)*; in biological materials, K. Bambach, *ibid.* **11**, *401 (1939)* and *C. A.* **33**, *73, 7234*. See also Biefeld and Patrick, *Ind. Eng. Chem.*, (*Anal. Ed.*) **14**, *275–8 (1942)*. Reagt. recomm. (*I. C.*).

s-**DIPHENYLCARBAZIDE** is used indirectly for detn. of Pb by pptn. as the chromate which is then dissolved for colmtc. estn. of the chromate, or xs. standard chromate may be used for pptn. and the xs. detd.; cf. under *chromium*; *Snell, pp.*

198–200; Yoe I, pp. 255–7. For use of this method in detg. Pb in blood, tissues, and excreta, cf. Letonoff and Reinhold, *Ind. Eng. Chem.*, (*Anal. Ed.*) **12,** *280–4* (*1940*), and Letonoff, *ibid.* **13,** *631* (*1941*).

TETRAMETHYLDIAMINODIPHENYLMETHANE, 1% soln. in glacial AcOH, forms a blue diphenylmethane dye with PbO_2; 5 mcg. Pb will produce the color and the intensity may be used for colmtc. estn.; other oxidizing agents give the same reaction; cf. *Snell, pp. 200–2.* Recomm. (*I. C.*). **BENZIDINE** may be used in a similar way and is likewise non-specific for PbO_2; cf. *Feigl, p. 29.*

CARMINIC ACID, 0.5% soln. in dil NH_4OH, is a reagt. for detc. of Pb by spot test. The test soln. is added to paper previously impregnated with the reagt., exposed to NH_3, and allowed to dry; a violet spot distinctly different from the red color of the reagt. denotes at least 1 mcg. of Pb in the drop used; Cu prevents test; intfr. of Ag, Bi, and Cd may be prevented; cf. F. Pavelka, *Mikrochemie* **7,** *301* (*1929*); *Feigl, p. 32.* Recomm. (*I. C.*).

With **GALLOCYANINE** (0.1% aq. soln.) and **PYRIDINE** (1% aq. soln.) a violet spot is obtained when a drop of the test soln. is put on paper, followed by pyridine soln., then by gallocyanine, and finally several more drops of pyridine soln. In the presence of Ag, Cu, Cd, and Bi, Pb may be pptd. in the paper as $PbSO_4$ and other ions removed by washing with several drops of water, after which pyridine and gallocyanine are added as directed above; cf. F. Pavelka, *Mikrochemie* **7,** *301* (*1929*); *Feigl, p. 32.* Pyridine with NH_4CNS may be used for rapid gravmtc. detn. of Pb; *Prodinger, p. 160.*

ANTHRANILIC ACID, 3% soln. in dil. NaOH soln., ppts. $Pb(C_7H_6O_2N)_2$ which may be dried and weighed or may be dissolved in NH_4OAc soln. and titrated with $KBrO_3$-KBr in an acid soln.; Zn, Cu, and Mn also ppt.; cf. Funk and Römer, *Z. anal. Chem.* **101,** *85–8* (*1935*); *Prodinger, p. 37.*

SALICYLALDOXIME as a 1% soln. in dil. alc. may be used for the quant. sepn. of Pb from Cu, Zn, Ag, Cd in strongly ammoniacal soln.; Biefeld and Ligett, *Ind. Eng. Chem.*, (*Anal. Ed.*) **14,** *359–61* (*1942*).

THIOUREA as the solid or as satd. soln. in *N* HNO_3 ppts. Pb and permits its sepn. from Ag, Hg, Cu, Bi, Zn, Ba, Cr, Mn, Al, Co, Ni, Fe, Sn, As, Sb, and Cd. Cf. *Prodinger, p. 154,* and Mahr and Ohle, *Z. anorg. Chem.* **234,** *224–8* (*1937*).

LITHIUM

AMMONIUM STEARATE, prepared by passing NH_3 into an ether soln. of stearic acid until all the ammonium stearate has pptd., is dried and redissolved in amyl alcohol; the reagt. must be made up fresh every day. Li stearate differs from all other alkali stearates in being much less soluble in amyl alcohol; for procedure in detn. of Li cf. E. R. Caley, *J. Am. Chem. Soc.* **52,** *2754–8* (*1930*); *Snell, p. 447.* **2-ETHYLHEXANOL** is said to be superior to amyl alc. as a solvent for the amm. stearate; Caley and Axilrod, *Ind. Eng. Chem.*, (*Anal. Ed.*) **14,** *242* (*1942*).

MAGNESIUM

8-HYDROXYQUINOLINE (OXINE), 2 to 5% alc. or AcOH soln., is a reagt. used extensively for macro- and micro-detn. and for the sepn. of Mg from metals of the alkali and alkaline earth groups. It gives a green-yellow ppt. from an ammoniacal soln. which may contain Ca, Ba, Sr, but must not contain Fe, Al, Mn, Cu, Zn, Ti, and phosphate. The ppt. when dried at 130–40° C. has the composition $Mg(C_9H_6ON)_2$; at lower temperatures it retains water of crystallization. By heating with oxalic acid, the ppt. may be ignited to the oxide for weighing. Many colmtc. methods are available for detn. of Mg in the presence of Ca as in urine, blood, etc.; for details and bibliography cf. *Snell, pp. 471–5;* Hillebrand and Lundell, *Applied Inorganic Analysis, pp. 114–5* (*1929; Wiley, New York*); cf. also *C. A. indexes.*

TITAN YELLOW (CLAYTON YELLOW, THIAZOLE YELLOW), 0.1 to 0.2% aq. soln., is a reagt. which is added to a neutral or acid soln. which is then made

alkaline with NaOH and in the presence of Mg produces an orange to red color or ppt. The method is suitable for colmtc. estn. of 0.001 to 0.015 mg. Mg. Dialyzed agar may be used as an aid in the prevention of pptn.; the filtrate from pptn. with oxalate may be used. Ca has a slight intensifying effect on color; Al, Ni, Co, Mn, Sn, Zn, and a high concn. of NH_4 salts intfr. The method is recommended for Mg detn. in urine (0.1 ml. sample is sufficient), blood, serum, milk, meat, and soil extracts; cf. *Snell, p. 476;* recomm. (*I. C.*). Gillam reports this reagt. to be good for Mg in photoelectric colmty., *Ind. Eng. Chem.*, (*Anal. Ed.*) **13,** *499–50* (*1941*), and Otto and Otto, *ibid., p. 65* (*1941*), find it good for detc. by test tube or spot plate methods after removal of most of metal ions.

Magnesium in pptd. $MgNH_4PO_4$ may be detd. colmtcly. by reduction of the phosphomolybdate to the usual blue color by means of reducing agents such as $SnCl_2$, **HYDROQUINONE,** or **AMINONAPHTHOLSULFONIC ACID;** the method is suitable for detn. of 0.015 mg. Mg; for details of the method and for bibliography cf. *Snell, pp. 468–9; Yoe I, pp. 264–6,* and biochemical laboratory manuals.

***p*-NITROBENZENEAZORESORCINOL (MAGNESON),** 0.5% soln. in 1% NaOH soln. (for low concns. of Mg dilute reagt. 5 to 10 times), is added to an acid soln. which is then made alkaline with NaOH to form a bright blue color or ppt. suitable for detc. of as little as 0.002 mg. Mg after removal of Ag, Cu-Sn, Fe, Co-Ni groups. Al and Ba, Sr, and Ca do not intfr; arsenate, chromate, and permanganate anions intfr. as does NH_4 when in concn. 70 times higher than Mg; cf. Newell, Pike, and Ficklen, *Z. anorg. allgem. Chem.* **225,** *284–4* (*1935*), and Mehlig and Johnson, *Ind. Eng. Chem.*, (*Anal. Ed.*) **12,** *30* (*1940*). Test papers may be made by soaking filter paper in 0.01% alc. soln. of reagt. and allowing to dry. For test, add a drop of unknown and then one of 1% NaOH; compare with a blank; cf. I. Stone, *Science* **72,** *322* (*1930*). ***p*-NITROBENZENEAZO-α-NAPHTHOL** is considerably more sensitive to Mg than the preceding reagt.; cf. *Feigl, p. 143.* Other similar compounds have been suggested; cf. *C. A.* **30,** *6302* (*1936*).

QUINALIZARIN, (1,2,5,8-TETRAHYDROXYANTHRAQUINONE), 10 to 20 mg. in 100 ml. alc., gives a blue color or ppt. with Mg when the reagt. soln. is added to a neutral or slightly acid test soln., then 2 *N* NaOH added in drops until alkaline. This reagt. is not as sensitive nor as specific as the reagts. previously listed. Alkaline earths, as well as metals of higher groups, must be removed by pptn. before making the test and a blank must be run; cf. Hahn, *Ber.* **57B,** *1394–6* (*1924*); *Feigl, p. 142,* cf. also *C. A.* **29,** *7214 and* **30,** *4116* (*1936*). Recomm. (*I. C.*).

CURCUMIN, 1% alc. soln., gives a yellow to orange color useful for colmtc. detn. of Mg in amounts approximating 0.05 mg; the color is formed when the reagt. is added to the test soln. and made alk. with NaOH; starch glycerite is used as a protective colloid. Phosphate in large amount does not intfr. if approximately equal amount is used in standards; borates in small amounts do not intfr.; Fe and other metals giving colored hydroxides intfr.; cf. I. M. Kolthoff, *J. Am. Chem. Soc.* **50,** *395* (*1928*); W. E. Thrun, *Ind. Eng. Chem.*, (*Anal. Ed.*) **4,** *426* (*1932*); *Snell, p. 477.*

OLEIC ACID, 2 g. and 0.5 g. KOH per liter 60% alc., is a reagt. for a nephelometric method suitable for detg. 0.02 to 0.1 mg. Mg; Ca must be absent; cf. *Snell, p. 478.*

MANGANESE

FORMALDOXIME (Deniges reagt.), prepd. by dissolving 20 g. trioxymethylene and 47 g. hydroxylamine sulfate in 100 ml. H_2O by boiling, gives a red coltn. to an alk. soln. of Mn (II). This color is suitable to the estn. of Mn in plant, soil, and biological materials. Colorations by Co, Cu, Fe, Cr, and Ni may be masked; cf. C. P. Sideris, *Ind. Eng. Chem.*, (*Anal. Ed.*) **9,** *445* (*1937*), and **12,** *307* (*1940*). Also see *C. A.* **32,** *77.* Recomm. (*I. C.*).

BENZIDINE, 2.3 g. dissolved in 100 ml. 5% HCl, may be used for detc. and detn. of Mn when the concn. of the element is too low for a satisfactory use of permanganate colorimetry. A blue-green color is given by manganate ion in concns. as

low as 0.008 ppm; the color fades within 2 minutes and a color comparison is made with artificial standards of $CuSO_4$ and picric acid. Other oxidizing agents give a similar reaction and must be absent; the sample should contain 0.1 to 1.0 mcg. Mn; cf. *Snell, pp. 343–4;* cf. also N. A. Clark, *Ind. Eng. Chem.*, (*Anal. Ed.*) **5**, *241* (*1933*). As a spot test, conditions may be controlled to make the reagt. practically specific among common metallic ions; cf. *Feigl, pp. 106–8.* Recomm. (*I. C.*).

TETRAMETHYLDIAMINODIPHENYLMETHANE, dissolved in $CHCl_3$ or in dilute AcOH, is oxidized by Mn in its higher valences to form a blue color which is much more stable than that obtained with benzidine; the reaction is carried out in a soln. acid with AcOH; for the spot test, cf. *Feigl, p. 105.* Recomm. (*I. C.*). For the colmtc. detn., cf. R. G. Harry, *J. Soc. Chem. Ind.* **50**, *434–6T* (*1931*); *Snell, p. 342.*

***o*-TOLIDINE** may, in the absence of free chlorine and other intfrnces., be used for colmtc. detc. and detn. of Mn as manganate; cf. *Snell, p. 341;* L. Forman, *J. Am. Water Works Assoc.* **21**, *1212–7* (*1929*).

STRYCHNINE, 1% soln. in conc. H_2SO_4, gives a blue-violet, changing to red, color with Mn which has been evaporated to dryness in the presence of NaOH. The test is specific in the absence of Co, chromate, and ferrocyanide; by the use of drop quantities, it is said to be sensitive to 0.2 mcg. Mn; cf. S. Augusti, *Ann. chim. applicata* **24**, *535–8* (*1934*).

ANTHRANILIC ACID may be used for the gravmtc. detn. of Mn in the absence of Zn, Cd, Ni, Co, and Cu which contaminate the ppt.; pptn. should be made at a pH above 5.2; cf. Funk and Demmel, *Z. anal. Chem.* **96**, *335–8* (*1934*); H. Goto, *J. Chem. Soc. Japan* **55**, *1156–63* (*1934*); *C. A.* **29**, *1029* (*1935*).

MERCURY

DIPHENYLTHIOCARBAZONE (DITHIZONE), 10 to 50 mg. per liter $CHCl_3$ or CCl_4, may be used for the detc., detn., and sepn. of small amounts of Hg which is extracted from acidic aq. phase by shaking with the reagt. soln. with consequent change in color from the original bluish-green to yellowish-orange; in soln. approximately pH 3, Cu is the only metal likely to intfr.; cf. Fischer and Leopoldi; *Z. anal. Chem.* **103**, *241* (*1935*); *Feigl, p. 23; A. O. A. C., pp. 409–412; Prodinger, p. 126.* Recomm. (*I. C.*). **DI-β-NAPHTHYLTHIOCARBAZONE** is similar to dithizone but is said to give a more distinctive color with Hg and to be superior for its colmtc. detn., D. M. Hubbard, *Ind. Eng. Chem.*, (*Anal. Ed.*) **12**, *768–71* (*1940*).

DIPHENYLCARBAZIDE (saturated soln. in alc.) and **DIPHENYLCARBAZONE** (saturated soln. in alc.) are also used in colmtc. detc. and detn. of Hg and as indicators in mercurimetric titration. Hg (II) gives a violet or blue color in neutral or slightly acid soln.; Zn, Fe, Co, Ni, Pb, Cu, Ag, chromate, cyanide, chloride, bromide, and iodide ions intfr.; cf. Stock and Zimmermann, *Z. angew. Chem.* **41**, *546–8* (*1928*); *Snell, p. 180,* and *Feigl, p. 22;* for adaptation to qual. scheme, cf. A. W. Scott, *J. Am. Chem. Soc.* **51**, *3351* (*1929*); for use as indicator, cf. Dubsky and Trtilek, *Chem. Listy* **27**, *385–8* (*1933*). If acidity and other conditions be controlled carefully, the carbazide may be used for colmtc. detn. of low concns. of Hg; cf. Laird and Smith, *Ind. Eng. Chem.*, (*Anal. Ed.*) **10**, *576* (*1938*). Recomm. (*I. C.*).

PROPYLENEDIAMINE with $CuSO_4$ gives with neutral or amm. soln. contg. about 0.1% Hg and xs. KI a ppt. of $HgI_4 \cdot Cu(Pn)_2$ which may be dried and weighed for detn.; Spacu and Spacu, *Z. anal. Chem.* **89**, *188* (*1932*). **ETHYLENEDIAMINE** may be used in a similar way; cf. Spacu and Sucui, *Z. anal. Chem.* **92**, *247* (*1933*).

For a determination using **PYRIDINE** with dichromate, cf. Spacu and Dick, *Z. anal. Chem.* **76**, *273* (*1929*); Furman and State, *Ind. Eng. Chem.*, (*Anal. Ed.*) **8**, *467* (*1936*), and *C. A.* **35**, *6892* (*1941*).

***p*-DIMETHYLAMINOBENZALRHODANINE,** satd. alc. soln., may be used as a drop test for detc. of Hg (II) in nearly neutral soln. free of Ag; a red color is formed; cf. Heller and Krumholz, *Mikrochemie* **7**, *217* (*1929*); *Feigl, pp. 24–7;* Kolthoff, *J. Am. Chem. Soc.* **52**, *2222* (*1930*).

ANTHRANILIC ACID ppts. Hg (II) as a slightly soluble salt which may be weighed for detn. of the metal; cf. Funk and Romer, *Z. anal. Chem.* **101**, *88 (1935)*. **THIOGLYCOLIC ACID β-AMINONAPHTHALIDE (THIONALID)** is also useful as a quant. precipitant of Hg; cf. Berg and Roebling, *Z. angew. Chem.* **48**, *430, 597 (1935)*. *Prodinger, pp. 38, 90.*

MOLYBDENUM, MOLYBDATE

POTASSIUM ETHYL XANTHATE (POTASSIUM XANTHATE) may be prepared as needed or the solid may be used as a reagt. giving a red colored complex soluble in $CHCl_3$. The reagt. is added to a neutral soln. contg. about 1 mcg. Mo per liter and the mixture is acidified to produce the color; for a colmtc. detn. the mixture is extracted with $CHCl_3$. The detn. is accurate to within about 8% and is specific fo Mo; it is used for detn. of small amounts of Mo in W; cf. D. Hall, *J. Am. Chem. Soc.* **44**, *1462 (1922); Snell, p. 383; Feigl, p. 64.* For spot test to detect Mo in steel, cf. *C. A.* **31**, *2120 (1937)*.

α-BENZOINOXIME (CUPRON), 2% alc. soln., is used for the pptn. and detn. of Mo in steel; the sample should contain about 0.15 g. Mo in hexivalent state and pptn. is made in a cold, slightly acid soln. which must not contain W, Pb, chromate, pentavalent V, or Ta; cf. H. B. Knowles, *Bur. Standards J. Research* **9**, *1 (1932)*.

CINCHONINE, 12.5% soln. in 6 *N* HCl, may be used to increase the extent and rapidity of pptn. by means of KCNS and a reducing agent such as $SnCl_2$; cf. C. M. Johnson, *Iron Age* **132**, *No. 2, 16 (1933)*.

PHENYLHYDRAZINE, in soln. in AcOH or dil. H_2SO_4, gives a red to rose coloration when warmed with molybdate soln. which is highly sensitive and specific; the color is suitable for detn. as well as detc. Iodates give free iodine, vanadates a green color, and permanganates are decolorized; tungstate is without effect; cf. E. Montignie, *Bull. soc. chim.* (4) **47**, *128 (1930); Snell, p. 389; Feigl, p. 65.*

TANNIC ACID, 0.5% aq. soln. freshly prepared, gives with a molybdate soln. contg. xs. AcOH a red, brown, or yellow color which is suitable for detn.; the sample should contain no more than 20 mg. Mo, W must have been sepd. previously; cf. G. Spurge, *Chem. Eng. Mining Rev.* **11**, *258 (1919); Snell, p. 389; Yoe I, p. 284.*

NICKEL

DIMETHYLGLYOXIME, 1 to 1.5% soln. in alc., is widely used for detc., gravmtc., titrimetric, and colmtc. detn. and sepn. of Ni. For a quant. pptn., the reagt. is added to a slightly acid soln. contg. no more than 30 mg. Ni, then NH_4OH or NaOAc is added to raise the pH to approximately 7. Co gives a brown, soluble complex; Fe (II) and a few other metals may contaminate the ppt. if they are present in excessive amounts or if the soln. is made too basic; ordinarily, however, Pd is the only element likely to intfr.; cf. Chugaev, *Ber.* **38**, *2520 (1905)*. For a discussion of the accuracy and limitation as a reagt., cf. E. G. Righellato, *Chem. Age* **28**, *574 (1933)*; for a summary of the use and precautions in pptn., cf. Hillebrand and Lundell, *Applied Inorganic Analysis, pp. 313–8 (1929, Wiley, New York)*; for spot tests by means of this reagt. with and without an accompanying oxidizing agent cf. *Feigl, pp. 88–92*; for detn. by colorimetry, cf. *Yoe I, p. 295*, and *Prodinger, 53*; for colorimetry in conjunction with an oxidizing agent (bromine water) which gives a red soluble complex making possible detn. of 0.015 to 0.5 mg. Ni without pptn., cf. *Snell, pp. 314–7*; for titrimetric method, cf. *C. A.* **29**, *1748 (1935)*; for detn. of Ni in soils, cf. *C. A.* **30**, *6488 (1936)*. Reagt. recomm. (*I.C.*).

A number of other reagts. have been suggested for Ni; for **α-BENZILDIOXIME (DIPHENYLGLYOXIME)**, cf. F. W. Atack, *Analyst* **38**, *316, (1913)*; for **METHYLBENZOYLGLYOXIME**, cf. H. Holzer, *Z. anal. Chem.* **95**, *392 (1933)*; for **CYCLOHEXANEDIONEDIOXIME**, which is very similar to dimethylglyoxime but has the advantage of high water solubility, cf. O. Wallach, *Ann.* **437**, *148 (1924)*, *C. A.* **19**, *487 (1925)*; **α-FURILDIOXIME** is also soluble in water and has an added advantage

in gravmtc. detn. of Ni in that Ni makes up only 11.81% of its compound with the reagt. whereas with dimethylglyoxime the percentage is 20.31; cf. Soule, *J. Am. Chem. Soc.* **47**, *981 (1925)*. For critical comparison of Ni reagts., cf. Wenger, et al., *Helv. Chim. Acta* **24**, *889–99 (1941)*, *C. A.* **36**, *2225*.

SALICYLALDOXIME, prepd. as described under *copper*, quant. ppts. Ni at pH 7; the ppt. may be contaminated by iron if this element is present in test soln.; cf. Biefeld and Howe, *Ind. Eng. Chem.*, (*Anal. Ed.*) **14**, *251–3 (1942)*.

DITHIOOXAMIDE (RUBEANIC ACID), 1% alc. soln., may be used as a sensitive spot reagt. and gives a blue-violet spot in ammoniacal soln.; Co, Fe, and Cu intfr.; cf. *Feigl, p. 92*. Recomm. (*I. C.*).

FORMALDOXIME, made as needed by boiling a mixture of 7 g. hydrazine hydrochloride, 15 ml. water, and 3 g. trioxymethylene, may be used for detc. and detn. of as low as 0.1% Ni in Co salts; it gives a brown color; cf. G. Deniges, *C. A.* **27**, *927 (1933)*. Recomm. (*I. C.*).

POTASSIUM DITHIOOXALATE, 0.1% aq. soln. made up fresh every few days, is said to be better for colorimetry than dimethylglyoxime. It gives a deep bluish-red color. The sample should contain about 1 mg. Ni; the color develops in a slightly acid soln. Co and Fe must be removed and most of the common metals intfr. if present in appreciable amounts; Mg, alkaline earths, Al, and phosphate do not intfr.; cf. *Snell, pp. 317–9, Yoe I, p. 298–303*.

ANTHRANILIC ACID ppts. a slightly soluble Ni salt from a slightly acid soln.; Cu, Mn, Zn, and Co intfr.; Funk and Ditt, *Z. anal. Chem.* **93**, *241–7(1933)*.

ETHYLENEDIAMINE with thiosulfate may be used for a spot test for Ni and gives a violet ppt.; cf. G. Spacu and P. Spacu, *Z. anal. Chem.* **89**, *192 (1932)*.

NITRATE, NITRITE

Various reagts. are precipitants for nitrate. **NITRON,** 1 g. in 10 ml. 5% AcOH, is a reagt. which is unstable and must be prepared as needed; a formic acid soln. is said to be more stable. This reagt. forms a nitrate which is soluble only to the extent of 9.9 mg. per 100 ml. water; perchlorate and some other anions similarly give slightly soluble salts and intfr. in detn.; cf. Busch, *Ber.* **38**, *861 (1905)*; Cope and Barab, *J. Am. Chem. Soc.* **39**, *504–14 (1917)*. **DI-(α-NAPHTHYLMETHYL)-AMINE,** about 10% in 50% AcOH, is said to be a more effective precipitant than nitron but it is likewise non-specific; only its acetate, sulfate, and phosphate are soluble in water; cf. Rupe and Becherer, *Helv. Chim. Acta* **6**, *674* and *885 (1923)*; F. Konek, *Z. anal. Chem.* **97**, *416–8 (1934)*. For **α-PHENYL-β-DIETHYLAMINOETHYL-*p*-NITROBENZOATE** see under *chlorine* and *perchlorate*.

PHENOLDISULFONIC ACID, prepared by dissolving pure **PHENOL** in conc. H_2SO_4, gives a yellow color with minute amounts of nitrate in alk. soln.; for detn. in water of low chlorine content and samples contg. 0.05 mg. or less of nitrate, cf. *A. O. A. C., p. 527; A. P. H. A., pp. 48–9; Yoe I, pp. 313–6; Snell, pp. 629–35*. The color of **INDIGO CARMINE** is bleached by nitrate and this is used to detc. nitrate impurities in various salts; cf. *U. S. Pharmacopoeia XI, p. 493*; **DIPHENYLAMINE** or **DIPHENYLBENZIDINE** in sulfuric acid gives blue colors by reaction with nitrate in acid soln.; 0.5 to 5 mcg. may be detected and determined; for details and bibliography, cf. *Snell, pp. 637–41; Yoe I, p. 316; Feigl, p. 211*; for detc. of nitrate in milk, cf. *C. A.* **29**, *7510 (1935)*, and in wines, cf. *A. O. A. C., p. 170*.

BRUCINE, 0.02% soln. in H_2SO_4 for spot test, and 5% soln. in $CHCl_3$ for colmtc. detn. gives a red color with nitrate in acid soln. which changes to a stable yellow useful for colmtc. detn. The sample should contain 0.01 to 0.2 mg. nitrate nitrogen; nitrite reacts similarly if acid concn. is low; cf. *Feigl, p. 212; Snell, p. 635; Yoe I, p. 318*. **STRYCHNINE** also gives a very delicate test; cf. *Snell, p. 636, Yoe I, p. 320*.

For detn. of nitrate in nitrite the latter is destroyed by sodium azide then the nitrate reacted with **NITROBENZENE** to obtain dinitrobenzene which is detd. by

means of acetone and alkali, cf. W. Seaman, et al., *Ind. Eng. Chem.*, (*Anal. Ed.*) **14,** *420–22 (1942).*

AZORUBIN, 0.01% aq. soln., with H_2SO_4 is decolorized by nitrate or nitrite, and has the advantage over many of the other reagts. in that Fe (III) ion has no effect; cf. J. Skutil, *Chem. Listy* **30,** *74 (1936).*

Nitrite is usually detc. or determined colmtcly. by its diazotization of amines which are then coupled with other amines or phenols to form colored azo compounds; **α-NAPHTHYLAMINE** and **SULFANILIC ACID** are widely used for this purpose; for nitrite in flour, cf. *A. O. A. C.*, p. *222;* for nitrite in water, cf. *A. O. A. C., p. 527; A. P. H. A., p. 46; Yoe I, p. 308; Snell, p. 644; Feigl, p. 215.* **DIMETHYL-α-NAPHTHYLAMINE** is said to be superior to the naphthylamine in the preceding reaction; cf. F. G. Germuth, *Ind. Eng. Chem.*, (*Anal. Ed.*) **1,** *28 (1929).* **SULFANILAMIDE** with ***N*-(1-NAPHTHYL)-ETHYLENEDIAMINE DIHYDROCHLORIDE** have recently been found superior reagts. for nitrite; Martha B. Shinn, *Ind. Eng. Chem.*, (*Anal. Ed.*) **13,** *33 (1941).* This procedure has been adapted to waterworks usage, cf. Kershaw and Chamberlin, *Ind. Eng. Chem.*, (*Anal. Ed.*) **14,** *312 (1942).*

OSMIUM

THIOUREA when boiled with sodium chloroosmate and xs. HCl gives an intense red color when the concn. is above 10 ppm; cf. Chugaev, *Z. anorg. allgem. Chem.* **148,** *65 (1925);* for complete procedure for Os, Ru, Pt, Pd, Rh, and Ir, cf. Gilchrist and Wichers, *J. Am. Chem. Soc.* **57,** *2565–73 (1935).* For reaction with **NICKEL ACETATE,** see under *palladium.*

OXALATE

DIPHENYLAMINE, as the solid, may be mixed and heated with the unknown and the residue extracted with a little alc. to get a blue soln. if oxalate was present in the sample. Recomm. (*I. C.*). *Feigl, p. 336–8.*

INDIGO is not bleached by $K_2Cr_2O_7$ alone but in the presence of as little as 0.03 mg. oxalate, both oxalate and indigo are oxidized with consequent loss in color of the indigo; cf. Tavanaev and Budkevich, *Z. anal. Chem.* **103,** *353 (1935); ibid.,* **104,** *413 (1936).*

Oxalic acid may be reduced to glycolic acid by the use of Mg powder, and this glycolic acid may be detected by the use of **2,7-DIHYDROXYNAPHTHALENE** in H_2SO_4; cf. *Feigl, p. 335.*

OXYGEN

A mixture of $Mn(OH)_2$ and KI may be used for detc. or detn. of oxygen in a gaseous mixture; after absorption of oxygen, acid and **STARCH** are added and the detn. is made by comparison of the color of the starch-iodine complex; cf. *Snell, pp. 133–6; C. A.* **28,** *5778* and *6889 (1934).*

PYROGALLOL, in alkaline soln. is in general use for removal of oxygen from other gases and is also used for the estn. of oxygen-supplying power of soil; cf. Hutchins and Livingston, *J. Agr. Research* **25,** *133 (1923).*

For dissolved oxygen, the yellow leuco base of **INDIGO CARMINE** has been successfully used on 1 ml. samples of liquid; errors are low; extreme care must be taken to prevent contact of the reagt. soln. with air; for preparation of reagt. and details of procedure, cf. V. V. Efimov, *Biochem. Z.* **155,** *371–5 (1925)* or *Snell, p. 137.* **ADUROL** has been used for approximate estn.; cf. *Snell, p. 136* or *Yoe 1, p. 330.* **AMIDOL (2,4-DIAMINOPHENOL HYDROCHLORIDE)** has been used for a field method in determining oxygen in water and sewage; cf. *A. P. H. A., p. 237;* M. L. Isaacs, *Sewage Works J.* **7,** *435–43 (1935);* F. W. Gilcreas, *J. Am. Water Works Assoc.* **27,** *1166 (1935).*

ORGANIC REAGENTS FOR INORGANIC ANALYSIS

PALLADIUM

DIMETHYLGLYOXIME gives a bright yellow ppt. from acid soln. of Pd and provides a method for separating Pd from Os, Ru, Pt, Rh, and Ir, and for its subsequent detn.; Au must be absent as it is pptd. as the metal; cf. Gilchrist and Wichers, *J. Am. Chem. Soc.* **57**, *2565–73 (1935)*. Recomm. (*I. C.*). **β-BENZILDIOXIME** may also be used and gives a ppt. with 3 mcg. Pd per ml.; cf. Dwyer and Mellor, *C. A.* **29**, *4690 (1935)*; other oximes which may be used are **BENZOYL-METHYLGLYOXIME**, cf. *Chem. News* **131**, *401 (1925)* and **SALICYLALDOXIME**, cf. Holzer, *Z. anal. Chem.* **95**, *398 (1933)*. **β-FURFURALDOXIME** may be better than the dimethylglyoxime in detc. and detn. of Pd, cf. Hayes and Chandlee, *Ind. Eng. Chem.*, (*Anal. Ed.*) **14**, *491–3 (1942)*.

***p*-DIMETHYLAMINOBENZALRHODANINE**, satd. alc. soln. gives a reddish-violet ppt. with Pd in neutral or sl. acid soln. contg. at least 0.1 ppm Pd; Pt, Au, Ag, and Hg also ppt.; cf. *Feigl, pp. 18–81.* **5-(4-SULFO-1-NAPHTHYLAZO)-8-HYDROXYQUINOLINE**, alc. soln., gives an orange color or red ppt. with as little as 2 mcg. Pd in dil HNO_3 soln. and is specific; cf. Gutzeit and Monnier, *Helv. Chim. Acta* **16**, *233 (1933)*; *Feigl, p. 81.* **6-NITROQUINOLINE** gives a yellow ppt. of $Pd(C_9H_6N \cdot NO_2)_2$ which may be dried for gravmtc. detn. and which is specific in the platinum group; cf. Ogburn and Riesmeyer, *J. Am. Chem. Soc.* **50**, *3018 (1928)*. ***p*-NITROSODIPHENYLAMINE** and related compounds have been found of merit in detc. and colmtc. detn. of Pd (II); cf. Yoe and Overholser, *J. Am. Chem. Soc.* **61**, *2058–63 (1939)*, and **63**, *3224 (1941)*.

The reduction of nickel in **NICKEL ACETATE** by sodium hypophosphite is catalyzed by Pd and this property may be used as a means of detecting Pd. The test is made in a clean test tube to which is added 1% soln. of $Ni(OAc)_2$, satd. NaH_2PO_2, and unknown. When warmed in boiling water, the Ni is deposited as a black powder or as a mirror within 2–30 min. A blank shows test only after a long time. Pt, Ru, and Os also give test but not as quickly; cf. *Feigl, p. 75.* Recomm. (*I. C.*).

PHOSPHORUS, PHOSPHATE

For amounts up to 1 or 2 mg. phosphate, detn. may generally be made most satisfactorily by formation of phosphomolybdate which is subsequently reduced by such reagts. as **1-AMINO-2-NAPHTHOL-4-SULFONIC ACID, HYDROQUINONE,** or **BENZIDINE** to produce colors suitable for colmtc. estn.; cf. *A. O. A. C., p. 133; A. P. H. A., pp. 109–11; Feigl, p. 216.* For a comprehensive review of colmtc. methods, cf. *Snell, pp. 480–516*, and for a comparison of various pptn., titrimetric, and colmtc. methods with bibliography, cf. Peters and Van Slyke, *Quantitative Clinical Chemistry, p. 857 ff (1932, Williams and Wilkins, Baltimore)*. For the use of **STRYCHNINE MOLYBDATE** in nephelometry of phosphate, cf. *Yoe II, pp. 148–54.* The 1-amino-2-naphthol-4-sulfonic acid—ammonium molybdate reaction has been used for the detn. of phosphorus in soils; cf. Mildred S. Sherman, *Ind. Eng. Chem.*, (*Anal. Ed.*) **14**, *182 (1942)*.

PLATINUM

NICKEL ACETATE, see under *palladium.* Recomm. (*I. C.*). For analysis scheme for platinum metals, cf. Beamish and Scott, *Ind. Eng. Chem.*, (*Anal. Ed.*) **9**, *460–3 (1937)*.

POTASSIUM

***p*-DIPICRYLAMINE (HEXANITRODIPHENYLAMINE or "AURANTIA"),** 0.2 g. in 20 ml. water contg. 2 ml. of *N* Na_2CO_3, gives an orange-red crystalline ppt. with K in sl. alk. sol.; as a spot test it will detect 3 mcg. K. NH_4 in large xs. must be removed but Li, Na, Mg, Ca, Sr, and Ba do not ppt.; cf. Poluektov, *Mikrochemie* **14**, *265–6 (1934)*; *Feigl, p. 149.* The Mg salt of the amine may be used instead of the Na

salt as formed in Na_2CO_3 and has been satisfactorily used in gravmtc., volmtc., and colmtc. detn. of K in macro and micro amts.; cf. Kolthoff and Bendix, *Ind. Eng. Chem.*, (*Anal. Ed.*) **11**, *94–8 (1939)*. See also E. Amdur, *ibid.* **12**, *731–4 (1940)*. Recomm. (*I. C.*).

PICRIC ACID, saturated soln. in alc., ppts. K (as well as NH_4, Rb, and Cs) and the ppt. may be dissolved in water for colmtc. estn.; sulfates must be removed but Ca, Mg, Al, Fe, phosphates, and silicates do not intfr.; cf. E. R. Caley, *J. Am. Chem. Soc.* **53**, *539–45 (1931)*; *Snell, p. 437*; *C. A.* **29**, *1031 (1935)*; other nitrophenols have been tried, cf. Rosenthaler, *Mikrochemie* **2**, *29–32 (1924)*.

The familiar qual. reagt., sodium cobaltinitrite, may be used for sepn. of K and subsequent colmtc. detn. by reaction with many of the nitrite reagts.; cf. *Snell, pp. 432–7*. Washing of ppt. during sepn. should be done with 1% $Al_2(SO_4)_3$; W. E. Thrun, *Ind. Eng. Chem.*, (*Anal. Ed.*) **5**, *79 (1933)*. For indirect detn. of K in ppt. cf. C. P. Sideris, *ibid.* **9**, *145 (1937)*.

NAPHTHOL YELLOW S (2,4-DINITRO-1-NAPHTHOL-7-SULFONIC ACID), satd. aq. soln., gives a yellow ppt. with a soln. contg. as much as 400 ppm K; NH_4 and Na do not ppt.; cf. Clark and Willits, *Ind. Eng. Chem.*, (*Anal. Ed.*) **8**, *209 (1936)*.

SODIUM 5-NITRO-6-CHLOROTOLUENE-3-SULFONATE, satd. aq. soln., may be used for pptn. and detn. of K in the absence of NH_4 and Rb which are also pptd. by the reagt.; the K salt is 1/40 as sol. as the reagt.; cf. Davies and Davies, *J. Chem. Soc.* **123**, *2976–82 (1923)*.

"GARDINOL," "DREFT," or "DRENE," 3% aq. soln., form K salts which are much less soluble than the corresponding Li, NH_4 Mg, Ca, Na, and Ca salts, and may therefore be used as tests for K; cf. E. A. Wildman, *C. A.* **30**, *407 (1936)*; B. Reichert, *C. A.* **29**, *3939 (1935)*.

The hydrogen **TARTRATE** ion is in common use as a precipitant for K. The reagt. soln. is prepared by mixing 50 ml. of 2 *N* tartaric acid, 25 ml. 0.5 *N* NaOH, 25 ml. 96% alc. and allowing the mixture to stand until clear; cf. *C. A.* **23**, *1588 (1929)*; Clarke and Davidson, *Ind. Eng. Chem.*, (*Anal. Ed.*) **3**, *258–9* and *324–5 (1931)*; for use in conjunction with sodium cobaltinitrite, cf. Wikul, *Z. anorg. allgem. Chem.* **151**, *338 (1926)*.

RUBIDIUM

For the use of **5-NITRO-6-CHLOROTOLUENE-3-SULFONATE** see under *potassium*.

RUTHENIUM

RUBEANIC ACID (DITHIOOXAMIDE), 2.5% soln. in glacial AcOH, gives a blue soln. with as little as 0.2 mcg. of Ru in aq. soln.; other Pt metals do not give permanent colorations; H_2PtCl_6 gives a red soln. which soon yields a brownish-red ppt.; cf. Wölbling and Steiger, *Mikrochemie* **15**, *295–301 (1934)*. For a complete analysis of the Pt group, cf. Gilchrist and Wichers, *J. Am. Chem. Soc.* **57**, *2565–73 (1935)*.

THIONALID (THIOGLYCOLIC β-AMINONAPHTHALIDE) has been used in detn. of Ru; cf. W. J. Rogers, et al., *Ind. Eng. Chem.*, (*Anal. Ed.*) **12**, *561–3 (1940)*.

SCANDIUM

MORIN with minute amts. of Sc gives a green fluorescence in ultraviolet light. For review of tests for Sc, cf. G. Beck, *Mikrochim. Acta* **2**, *9–12*, *287–90 (1937)*; *C. A.* **32**, *452*, *1606 (1937)*.

SELENIUM

THIOUREA in the absence of excess nitrate and Cu gives a red ppt. of free Se from HCl solns. contg. minute amounts; Se may be separated from Te by this reagt.

and may be detd. by weighing the pptd. Se; cf. P. Falciola, *Ann. chim. applicata* **17**, *357–8 (1927); Feigl, p. 231.* Recomm. (*I. C.*).

PYRROLE, 1% soln. in alc., added to a soln. of the unknown in syrupy phosphoric acid contg. a little $FeCl_3$ gives a deep blue color when the concn. of Se as H_2SeO_3 is over 0.1 ppm; the color is suitable for estn.; silicic acid acts similarly; selenic, tellurous and telluric acids do not intfr.; cf. Berg and Teitelbaum, *Mikrochemie, Emich Festschr. 23–6 (1930); Snell, p. 604; Feigl, p. 336.*

CODEINE PHOSPHATE, 4% aq. soln., has been used for detc. and colmtc. detn. of SeO_2 as an impurity in conc. H_2SO_4. When 0.1 ml. of the reagt. soln. is added to 10 ml. sample, a blue coloration is obtained when the concn. of SeO_2 is over 0.00005%; As_2O_5 gives no color in concn. below 1%; Fe (III) gives a blue color when concn. is above 0.0015%; cf. Tz. Raikhinstein, *C. A.* **23**, *2391 (1929).*

For other methods, cf. Dudley and Byers, *Ind. Eng. Chem., (Anal. Ed.)* **7**, *3 (1935);* Williams and Byers, *Ind. Eng. Chem.* **28**, *912 (1936).*

SILICON, SILICATE

Ammonium molybdate with silicate in acid soln. gives the complex silicomolybdic acid which, after warming, gives with **BENZIDINE** a blue color in sl. ammoniacal soln.; phosphates and arsenates react similarly; cf. *Feigl, p. 219.* Recomm. (*I. C.*).

For use of **PYRROLE** see under *SELENIUM.*

SILVER

***p*-DIMETHYLAMINOBENZALRHODANINE,** satd. soln. in acetone, when added to a soln. slightly acid with HNO_3 gives a reddish-violet color or ppt. if the concn. of Ag is above 0.4 ppm; other metals, Hg, Au, Pt, Pd, and Cu, also react; in the presence of KCN only Cu is likely to intfr.; cf. *Feigl, pp. 16–19; Z. anal. Chem.* **74**, *380–6 (1928); Mikrochemie* **3**, *165–73 (1931);* Kolthoff, *J. Am. Chem. Soc.* **52**, *2222–6 (1930).* Recomm. (*I. C.*). For a spot test to detect Ag in galenites, cf. R. Jirkovsky, *Mikrochemie* **17**, *135–40 (1935);* for a colmtc. detn. of minute amounts of Ag, cf. *I. C.* Schoonover, *J. Research Natl. Bu. Standards* **15**, *377–84 (1935).*

DIPHENYLTHIOCARBAZONE (DITHIZONE), in $CHCl_3$ soln., gives a violet color with 0.05 to 0.1 mcg. Ag in acid soln.; Cu and Hg give similar reactions; cf. Fischer, Leopoldi and von Uslar, *Z. anal. Chem.* **101**, *1–23 (1935); Feigl, p. 21.* Recomm. (*I. C.*).

2-THIO-5-KETO-4-CARBETHOXY-1,3-DIHYDROPYRIMIDINE, as a freshly made 0.01% soln. in acetone, may be superior to the dimethylaminobenzalrhodanine in detc. and detn. of Ag. The yellow soln. gives a purple coloration with Ag concns. over about 0.4 ppm. At pH 2.0, Hg (I) and Hg (II) intfr. and must be absent; Cu and Fe (III) in comparatively large amts. intfr. Yoe and Overholser, *Ind. Eng. Chem., (Anal. Ed.)* **14**, *148 (1942).*

With Ag in sl. alk. soln. many reducing agents, such as **DEXTRINE, GUM ARABIC, SUGAR, STARCH,** and **GLYCEROL,** reduce the silver ion to the element in colloidal form suitable for colmtc. estn.; cf. *Yoe I, p. 683.*

SODIUM

ZINC or **MAGNESIUM URANYL ACETATE,** see references for methods of preparing the reagt., may be used for the detc., gravmtc. and colmtc. detn. of Na; Ca, Mg, Sr, Ba, and Fe do not intfr.; K, unless present in an amount over 5 times that of the Na, does not ppt.; phosphate is pptd. by adding lime to prevent intfr.; proteins may be pptd. by $HgCl_2$; cf. Barber and Kolthoff, *J. Am. Chem. Soc.* **50**, *1625–31 (1928); ibid.,* **51**, *3233–7 (1929);* Caley and Foulk, *J. Am. Chem. Soc.* **51**, *1664–74 (1929);* also cf. *Snell, pp. 439–42, Feigl, p. 147;* Peters and Van Slyke, *Quantitative Clinical Chemistry, Vol. II, p. 732 (1932, Williams and Wilkins, Baltimore);* for **COBALT URANYL ACETATE,** cf. *U. S. Pharmacopoeia XI, p. 453.*

6,8-DICHLOROBENZOYLENEUREA (SHEIBLEY'S REAGENT) in soln. in dil. KOH may be used for detc. of Na in presence of other alkali metals, cf. F. E. Sheibley, *J. Org. Chem.* **3**, *414–23 (1938); C. A.* **33**, *2895 (1939)*.

STRONTIUM

SODIUM RHODIZONATE, 5% aq. soln. made up when needed, gives a red-brown ppt. or red color in neutral soln. of Sr; the color disappears on acidulation; Ca does not intfr. and Ba interference is prevented by pptn. as chromate; cf. Feigl, *Mikrochemie* **2**, *187 (1924); Feigl, p. 138;* G. Gutzeit, *Helv. Chim. Acta* **12**, *829 (1929)*.

SULFUR, SULFIDE, SULFATE

Free sulfur may be detected by heating the substance in a melting point tube for 5 minutes at 210° C. with **BENZYLIMIDO-DI (4-METHOXYPHENYL)-METHANE** which forms a blue color that may be extracted with benzene; cf. Schonberg and Urban, *Ber.* **67B**, *1999–2003 (1935)*.

For detn. of S in petroleum distillates, a reagt. freshly prepared from 10 vol. freshly distilled CS_2 and 1 vol. **PYRIDINE** is used. When heated with a sample contg. S it gives a pink color with an intensity varying with S content; cf. Thornton and Latta, *Ind. Eng. Chem., (Anal. Ed.)* **4**, *441–2 (1932); Snell, p. 600*.

***p*-AMINODIMETHYLANILINE**, dry or 1% soln., with a little 0.1 *N* $FeCl_3$ may be used to detect 1 mcg. or to determine 0.1 to 1 ppm sulfur as sulfide because of the formation of methylene blue; cf. *Feigl, p. 198; Yoe 1, pp. 373–7; Snell, pp. 593–6; C. A.* **29**, *1745 (1935)*. Recomm. *(I. C.)*.

BENZIDINE, as the free base or as the hydrochloride dissolved in dil. HCl, is widely used for pptn. of sulfate as benzidine sulfate; the detn. may then be made by titration with standard NaOH to phenolphthalein end point, or may be made colmtcly. by various means; see references. Phosphate, if present, is removed with magnesium carbonate. For routine analysis of boiler waters, cf. *A. P. H. A., pp. 106–8;* Schroeder, *Ind. Eng. Chem., (Anal. Ed.)* **5**, *6* and *403 (1933)*. See also Peters and Van Slyke, *Quantitative Clinical Chemistry, Vol. II, pp. 892–6* and *902 (1932, Williams and Wilkins, Baltimore); Snell, pp. 621–4;* Marsden and Pollard, *J. Soc. Chem. Ind.* **56**, *464–8T (1937)*.

BARIUM RHODIZONATE is not dissolved by acids; sulfuric acid or sulfate ion, however, bleach the red color of the insoluble barium salt by formation of $BaSO_4$. This may be used as a spot test for sulfate; cf. *Feigl, p. 204;* or, the reaction is the basis for use of sodium rhodizonate as an indicator for titration with $BaCl_2$; cf. Strebinger and Zombory, *Z. anal. Chem.* **105**, *346–50 (1936)*. **TETRAHYDROXYQUINONE** may be used in the same way to detect sulfate up to 30,000 ppm and has the advantage of being more stable; cf. Sheen and Kahler, *Ind. Eng. Chem., (Anal. Ed.)* **8**, *127–30 (1936)*, and Peabody and Fisher, *ibid*, **10**, *651 (1938); A. P. H. A., pp. 108–9;* **EOSIN** has been tried as an indicator for titration of sulfate with $Pb(NO_3)_2$; cf. J. E. Ricci, *Ind. Eng. Chem., (Anal. Ed.)* **8**, *130–2 (1936)*.

Sulfite may be identified by its bleaching effect on such dyes as **MALACHITE GREEN, MELDOLA BLUE,** and **FUCHSIN**; cf. *Feigl, p. 201;* G. Gutzeit, *Helv. Chim. Acta* **12**, *736 (1929);* V. E. Malinovskii, *C. A.* **25**, *2076 (1931)*. Sulfite in thiosulfate soln. may be detected by use of **FORMALDEHYDE** which releases alkali as shown by phenolphthalein; *Feigl, 202*. Recomm. *(I. C.)*.

Thiosulfate may be detected by its formation of a ppt. in a neutral soln. with a reagt. made by adding **ETHYLENEDIAMINE** to a soln. of $Ni(NO_3)_2$ until a violet color develops; cf. G. Spacu and P. Spacu, *Z. anal. Chem.* **89**, *192–6 (1932)*.

TANTALUM

For tests and reagts. see under *columbium*.

ORGANIC REAGENTS FOR INORGANIC ANALYSIS

TARTRATE

GALLIC ACID, 0.01 g. in 100 ml. concd. H_2SO_4, gives blue to yellow-green coloration with tartrate sepd. out as the Ca salt and heated to 120°–150° C. Formaldehyde, carbohydrates, glycolic acid and certain other acids intfr. by giving colorations but malic, cinnamic, salicylic, and the fatty acids do not. *Feigl, 338.* Recomm. (*I. C.*).

RESORCINOL, 2% aq. soln., gives a red color when heated with a sample contg. tartrate to which concn. H_2SO_4 is added; oxidizing agents intfr.; oxalate gives a blue color. For detc. of tartrate in cheese, cf. *A. O. A. C., p. 302.* If KBr be used with reagt. under controlled conditions of acidity and temperature, the reaction becomes specific except for chloral; cf. Ware, *Chemist and Druggist* **120,** *74–129 (1934);* Pesez, *J. pharm. chim.* **21,** *542 (1935).*

TELLURIUM

THIOUREA gives a yellow crystalline ppt. with acid or neutral solns. contg. Te in concns. of over 2–5 ppm. Se, Bi, and Sb may intfr. Cf. P. Falciola, *Ann. chim. applicata* **17,** *359–60 (1927); C. A.* **21,** *3580 (1927).* Recomm. (*I. C.*).

THALLIUM

DIPHENYLTHIOCARBAZONE (DITHIZONE), 0.01% soln. in $CHCl_3$ may be used for detn. of 0.005 to 0.2 mg. Tl in the presence of not over 100 mg. of Hg, Ni, or Zn, nor over 0.6 mg. Pb or Bi; Tl is extracted from an ammoniacal soln. by the reagt.; cf. L. A. Haddock, *Analyst* **60,** *394–9 (1935).*

THIONALID (THIOGLYCOLIC ACID β-AMINONAPHTHALIDE), in alk. soln. contg. cyanide or tartrate, is practically specific for Tl and ppts. in concns. as low as 0.1 ppm; the ppt. is suitable for gravmtc., volmtc., or colmtc. methods; cf. Berg, and Roebling, *Z. angew. Chem.* **48,** *430* and *597 (1935).*

For a summary of the action of many reagts. on Tl (I) and Tl (III), cf. Munch and Ward, *J. Am. Pharm. Assoc.* **24,** *351–8 (1935).*

THORIUM

1-AMINO-4-HYDROXYANTHRAQUINONE as a 0.1% soln. in alc. gives with Th in weakly acid solns. a red fluorescence. Ga reacts similarly but is very much weaker in effect. Other metal ions do not intfr. unless they oxidize the reagt.; phosphate, fluoride, and sulfate intfr.; White and Lowe, *Ind. Eng. Chem., (Anal. Ed.)* **13,** *809 (1941).*

CUPFERRON (AMMONIUM NITROSOPHENYLHYDROXYLAMINE) gives a quant. pptn. of Th in acetic acid soln.; Ag, Pb, Hg, Sn, Bi, W, and Ce intfr.; cf. Baudisch, *Chem. Ztg.* **33,** *1298 (1908);* W. M. Thornton, *Chem. News* **114,** *13 (1916).*

PICROLONIC ACID, 2.6 g. per liter, gives a ppt. of Th salt which is less soluble than Ca and Pb salts; pptn. is from a soln. acid with AcOH. The reagt. does not serve to separate Th from other rare earths but in their absence is satisfactory for gravmtc. detn. of Th; cf. Hecht and Ehrmann, *Z. anal. Chem.* **100,** *87–8 (1935).* **8-HYDROXYQUINOLINE (OXINE)** gives a pptn. from AcOH soln. buffered with NH_4OAc which is said to provide a more convenient macro- and micro-detn. than that with picrolonic acid; cf. F. Hecht, *Z. anal. Chem.* **100,** *98–103 (1935).*

PHENYLARSONIC ACID may be used to separate Th from Zr; the former gives a ppt. only in a soln. buffered with acetate; cf. Rice, Fogg, and James, *J. Am. Chem. Soc.* **48,** *895 (1926).*

TIN

CACOTHELINE, satd. aq. soln., gives a violet color with Sn (II) which may be used as a spot test or for colmtc. detn. The reaction is most sensitive in the presence

of HCl; thiosulfate, sulfite, Cu (I), and lower oxides of Mo and W give the same test; cf. G. Gutzeit, *Helv. Chim. Acta* **12,** *720 (1929); Feigl, p. 59; Snell, p. 258;* Newell, Ficklen and Maxfield, *Ind. Eng. Chem., (Anal. Ed.)* **7,** *40 (1935);* cf. also *C. A.* **30,** *4783 (1936).* Recomm. *(I. C.).*

DIMETHYLGLYOXIME with $FeCl_3$ added to an acid soln. of unknown and then made ammoniacal gives red Fe (II) dimethylglyoxime from reduction of Fe (III) by Sn (II) or any other strong reducing agent; tartrate is added before the ammonia to prevent pptn. of $Fe(OH)_3$; cf. *Feigl, p. 60.* Recomm. *(I. C.).*

CUPFERRON (AMMONIUM NITROSOPHENYLHYDROXYLAMINE) may be used for gravmtc. detn. of Sn and for its separation from As, Sb, Pb, Mn, Zn, Co, and Ni; cf. N. H. Furman, *Ind. Eng. Chem.* **15,** *1071 (1923);* Pinkus and Claessens, *Bull. soc. chim. Belg.* **36,** *413 (1927); Prodinger, p. 82.*

4-CHLORO-1,2-DIMERCAPTOBENZENE (1-CHLOROBENZENE-3,4-DITHIOL) as 0.2% soln. in NaOH soln. gives a pink or red color with acid soln. contg. Sn (II). Sn (IV) slowly gives the test also. The test soln. may contain as much as 15% HCl. If xs. reagt. is used in test tube, only Cu, Bi and Ni intfr. Mills and Clark, *J. Chem. Soc.* **149,** *175 (1936);* Clark, *Tech. Pub. Intern. Tin Research Development Council, Ser. A, No. 41 (1936).* Recomm. *(I. C.).*

TITANIUM

CUPFERRON (AMMONIUM NITROSOPHENYLHYDROXYLAMINE), freshly prepared 6% aq. soln. ppts. the reddish-brown Ti compound from an acid soln. which may contain Al, Cr, Mn, and Ni without intfrnce.; Zr, Fe, V, W, and rare earths ppt. under the same conditions; cf. T. R. Cunningham, *Ind. Eng. Chem., (Anal. Ed.)* **5,** *305 (1933).*

For the use of **8-HYDROXYQUINOLINE (OXINE)** as a pptant. of Ti, cf. Berg and Teitelbaum, *Z. anal. Chem.* **81,** *1 (1930); Prodinger, p. 110.*

THYMOL, 5 g. dissolved in 5 ml. dil AcOH, then mixed with 95 ml. conc. H_2SO_4 and protected from sunlight, is a reagt. for colmtc. detn. of 0.2 to 2.5 mg. TiO_2. It gives a yellow to red color depending on the concn. and errors average 5%; only W is likely to intfr.; cf. Lehner and Crawford, *J. Am. Chem. Soc.* **35,** *138–41 (1913); Snell p. 363.*

DIHYDROXYMALEIC ACID prevents the formation of an orange color with V and H_2O_2, but does not affect the coloration arising from interaction of Ti and H_2O_2. Consequently Ti in admixture with V, in acid solns., may be detected by this reagt.; cf. Fenton, *J. Chem. Soc.* **93,** *1064 (1908); Snell, p. 365.*

GALLIC ACID, 1% aq. soln., may be used for colmtc. detn. of minute amounts of Ti in neutral solns. to which NaOAc soln. is added after addn. of the reagt.; yellow to red colors are produced and the reaction is 20 times more sensitive than H_2O_2 test; Fe, Mo, U, W, Cr, Ce, Al, Be, Th, Zr, Mn, Zn, Ni, Co, and Ca must be absent; cf. *C. A.* **29,** *7219 (1935).*

PYROCATECHOL, 10% aq. soln. contg. a small amount of H_2SO_4 and freshly prepared, gives an orange coloration with Ti in concns. over 50 ppm; no intfrnce. is caused by Al, NH_4, Ba, Be, Cd, Ce, Cs, Co, La, Pb, Mn, Mo, K, Rb, Na, Sr, Te, W, Zn, chloride, nitrate, nitrite, sulfate or sulfite; Sb, As, Bi, Cr, Cu, Fe, Li, Mg, Hg, Ni, Ag, Sn, Tl, Th, U, V, Se, phosphate do intfr.; *Feigl, p. 122;* Pike, Ficklen, and Newell, *Ber.* **68B,** *1023–6 (1935).*

CHROMOTROPIC ACID, 5% aq. soln., gives a brown-red color with HCl or H_2SO_4 solns. of titanic compounds; the test is interfered with by several metals; cf. *Feigl, p. 123.*

***p*-HYDROXYPHENYLARSONIC ACID,** 4% aq. soln., is useful in sepg. Ti from Fe (II), Fe (III), Al, Zn, Co, Ni, Be, Cr, Na, K, NH_4, PO_4, MoO_4 CrO_4, VO_4, uranyl. H_2O_2 must be absent; Zr and Sn intfr. Simpson and Chandlee, *Ind. Eng. Chem., (Anal. Ed.)* **10,** *642 (1938);* cf. also *C. A.* **35,** *4702 (1941).*

ORGANIC REAGENTS FOR INORGANIC ANALYSIS

TUNGSTEN, TUNGSTATE

CINCHONINE, 125 g. in 1 liter HCl soln. made from 500 ml. conc. HCl, 500 ml. water, is added in the digestion of an alloy or mineral of W with HCl or HNO_3 to increase the rapidity and completeness of pptn.; the ppt. is ignited to WO_3 for detn. and is a standard procedure; cf. Hillebrand and Lundell, *Applied Inorganic Analysis, pp. 548 ff (1929, Wiley, New York).* Simpson, Schumb, and Sieminski, *Ind. Eng. Chem., (Anal. Ed.)* **10,** *243–5 (1938)* have found that even small amts. of phosphate cause erratic results in the cinchonine method.

α-BENZOINOXIME (CUPRON), 5% alc. soln., may be used for the quant. sepn. of W (as tungstate) from Mo and V; cf. H. B. Knowles, *Bur. Standards J. Research* **9,** *1 (1932).*

RHODAMINE B, 0.01% aq. soln., is changed in color from a yellowish-red to a bluish-red by W in dil. HCl soln. and this may be used for detc. and rough estn. Mo does not intfr. unless in great xs.; Sb (V) gives the same coloration; cf. E. Eegriwe, *Z. anal. Chem.* **70,** *400 (1927);* G. Heyne, *Z. angew. Chem.* **44,** *237–8 (1931).* G. Heyne has also suggested the use of **HYDROQUINONE** in sulfuric acid which gives a red color with tungstate; Fe, Ti, Mo, nitrate, and chromate intfr.; the errors are not as large as with rhodamine B, but Mo intfrnce. is greater; cf. *Snell, p. 378.*

The tungstate ion catalyzes the reduction of **MALACHITE GREEN** by titanous chloride and this may be used as a means of detecting W; E. B. Sandell, *Ind. Eng. Chem., (Anal. Ed.)* **10,** *667 (1938).*

URANIUM

CUPFERRON (AMMONIUM NITROSOPHENYLHYDROXYLAMINE) does not ppt. hexavalent uranium (i.e. UO_2^{++}) and in H_2SO_4 acid soln. V, Fe, Ti, and Zr may be separated from U by pptn. with this reagt. When reduced to U^{4+}, however, it is pptd. and may in this manner be separated from Al, Cr, Mn, and P; cf. Hillebrand and Lundell, *Applied Inorganic Analysis, pp. 109–12 (1929, Wiley, New York).*

α-QUINALDINIC ACID, 5% aq. soln. of Na salt, may be used for the quant. pptn. of hexavalent U; cf. Ray and Bose, *Z. anal. Chem.* **95,** *400–14 (1933),* *C. A.* **28,** *1625 (1934).*

SALICYLIC ACID, 2% aq. soln. of the sodium salt, gives a red coloration with uranyl ion which may be used for estn.; errors may be as high as 7% and Fe must be absent; the reaction takes place in a neutral or sl. acid soln.; cf. Muller, *Chem. Ztg.* **43,** *739–40 (1919); Snell, p. 394.*

VANADIUM, VANADATE

DIMETHYLGLYOXIME with $FeCl_3$ reacts with tetravalent V in the same manner as Sn (II); vanadate (pentavalent) may be reduced to vanadium (IV) by boiling with concd. HCl, then test may be made by adding $FeCl_3$ and reagt. and making alkaline with NH_4OH. *Feigl, 68.* Recomm. *(I. C.).*

CACOTHELINE, satd. aq. soln., gives violet coloration with V (III) in HCl soln. Vanadate may be reduced to V (III) by means of Zn in HCl. Molybdates and tungstates intfr. by giving colored reduction products; Fe (II) in presence of PO_4^{---} or F^- also intfrs. by reducing reagt. Sn must be absent. *Feigl, p. 69.* Recomm. *(I. C.).*

8-HYDROXYQUINOLINE (OXINE) may be used for detc. of vanadate; in AcOH soln. a yellow pptn. occurs which on warming becomes a deep blue colored soln.; Mo, W, Ti and Fe may be removed to prevent intfrnce.; cf. *Feigl, p. 69; C. A.* **28,** *3409 (1934).*

AMMONIUM BENZOATE, satd. aq. soln., may be used for a gravmtc. detn. on a sample contg. 0.10 to 0.15 g. V_2O_5; the results are accurate to 0.001% and are not affected by the presence of Mg, Al, Cu, Mo, W, or Ti; Fe and Cr must be removed; for details, cf. F. M. Shemyakin, *C. A.* **29,** *2880 (1935).*

CUPFERRON (AMMONIUM NITROSOPHENYLHYDROXYLAMINE), ppts. pentavalent V in cold, dil. H_2SO_4 soln. from Cr, As, P, Al, and uranyl; in the absence of appreciable amounts of Fe, Ti, and Zr this may be used for detn. of V; for references see under *uranium.*

ZINC

α-QUINALDINIC ACID, aq. soln. of the ammonium salt, ppts. Zn from a soln. alk. to methyl red-methylene blue indicator; Fe (III), Al, Cr, Be, Ti, and uranyl do not ppt. in the presence of tartrate and Zn may be detd. in their presence; the ppt. is dried at 125° C. and weighed as $Zn(C_{10}H_6O_2N)_2 \cdot H_2O$; cf. Ray and Majundar, *Z. anal. Chem.* **100,** *324–7 (1935);* also *Mikrochemie* **18,** *89 (1935),* and Shennan, *Analyst* **64,** *14 (1939); Prodinger, p. 58.* For use of **5-NITROQUINALDINIC ACID** in colmtc. detn. of micro amts. of Zn see W. L. Lott, *Ind. Eng. Chem.,* (*Anal. Ed.*) **10,** *335–8 (1938).*

8-HYDROXYQUINOLINE (OXINE), 2% alc. soln., gives a quant. pptn. of Zn; in acetate buffer solns. (pH 5–6) Zn may be sepd. from alkaline earths, Pb and Mn. In alk. soln. Zn is said to be separable from Al, Cr, Fe, Sb, As, Bi, Co, Ni, Mn; cf. Berg, *Z. anal. Chem.* **71,** *171 (1927);* Spacu and Dick, *ibid.* **73,** *356 (1928),* and *Prodinger, p. 107.* For use in detn. of Zn in soils, cf. J. S. Hosking, *C. A.* **30,** *6488 (1936).*

ANTHRANILIC ACID ppts. Zn from neutral or sl. acid soln.; the ppt. may be dried as $Zn(C_7H_6O_2N)_2$ for gravmtc. detn. or may be titrated with KBr–$KBrO_3$ soln.; cf. Funk and Ditt, *Z. anal. Chem.* **91,** *332–7 (1933);* Cimerman and Wenger, *Mikrochemie* **18,** *53 (1935); Prodinger, p. 31.* For use of reagt. in detn. of Zn in "white metal" alloys cf. C. W. Anderson, *Ind. Eng. Chem.,* (*Anal. Ed.*) **13,** *367 (1941)*

DIPHENYLTHIOCARBAZONE (DITHIZONE) may be used for detc. and detn. of mcg. amounts of Zn. The Zn is extracted quant. by the reagt. in $CHCl_3$ soln. from the aq. soln. buffered to pH of about 5 and this results in changing the color of the reagt. soln. to red; cf. Fischer and Leopoldi, *Z. anal. Chem.* **97,** *385–95 (1934);* see also Fischer and Leopoldi for a method of preventing intfr. by any metal, *ibid.,* **107,** *241–69 (1937); C. A.* **31,** *969 (1937);* cf. also P. L. Hibbard, *Ind. Eng. Chem.,* (*Anal. Ed.*) **9,** *127–31 (1937); Snell, pp. 350–2.* For detn. of Zn in foods, in plant materials, and for a general discussion of specificity of the reagt. cf. Holland and Ritchie, *J. Assoc. Official Agr. Chem.* **22,** *333 (1939);* Cowling and Miller, *Ind. Eng. Chem.,* (*Anal. Ed.*) **13,** *145–9 (1941);* Wichmann, *ibid.* **11,** *66–72 (1939).* For spot test, cf. *Feigl, p. 110.* Reagt. recomm. (*I. C.*).

Potassium ferricyanide may be used with a number of easily oxidized amines to ppt. zinc ferrocyanide by interaction of amine and ferricyanide; the oxidation product of the amine is simultaneously absorbed by the zinc ferrocyanide. **DIETHYLANILINE, DIPHENYLAMINE, DIPHENYLBENZIDINE, METANIL YELLOW, ORANGE IV (TROPAEOLIN OO)** have been used in detc. of Zn and as titrimetric indicators; cf. Cone and Cady, *J. Am. Chem. Soc.* **49,** *356* and *2214 (1927);* E. Eegriwe, *Z. anal. Chem.* **74,** *225–31 (1928); Feigl, p. 109.* For detn. of Zn in rubber compds., ***p*-ETHOXYCHRYSOIDINE** (***p*-ETHOXYPHENYLAZO-*m*-PHENYLENEDIAMINE**) as a 0.2% soln. in about 60% H_2SO_4 has been found superior to the reagts. listed above as an indicator in titration with standard $K_4Fe(CN)_6$ soln., cf. W. P. Tyler, *Ind. Eng. Chem.,* (*Anal. Ed.*) **14,** *114–118 (1942).*

ZIRCONIUM

PHENYLARSONIC ACID, 2.5% soln., has been used for pptn. and detn. of Zr; cf. P. Klinger, *Tech. Mitt. Krupp.* **3,** *1–4 (1935). C. A.* **29,** *5039 (1935).* **PROPYLARSONIC ACID** yields a white ppt. from $ZrCl_4$ in dil. HCl soln.; Th, Ti, Mn, Ni, Fe, Al, Ce, V, Cr, Cu, Mg, Zn, U, Mo, Co, Be, and Cd do not intfr.; Sb, Bi, and Sn do intfr.; cf. Arnold and Chandlee, *J. Am. Chem. Soc.* **57,** *8* and *591,* (*1935*). ***p*-DIMETHYLAMINOAZOPHENYLARSONIC ACID** has found use as a spot reagt.; cf. *Feigl, p. 126* and for a rapid colmtc. detn. of Zr in steel, cf. Hayes and Jones, *Ind. Eng. Chem.,* (*Anal. Ed.*) **13,** *603 (1941).* Recomm. (*I. C.*). ***p*-HYDROXY-**

ORGANIC REAGENTS FOR INORGANIC ANALYSIS

PHENYLARSONIC ACID is useful in detn. of Zr as it is for Ti (q.v.); intfr. by Ti is eliminated by addn. of H_2O_2; Sn and PO_4 ions intfr. Cf. reference under Ti.

β-NITROSO-α-NAPHTHOL, 1% alc. soln., is used for detc. in dil. HCl soln. contg. at least 0.1 mg. Zr per ml.; a red color is given; Fe, sulfates, xs. of Ti must be removed before making the test; Al, Th, Ce, and La do not intfr.; cf. Bellucci and Savoia, *C. A.* **18,** *3333 (1924);* Oshman and Zerchaninova, *C. A.* **29,** *2881 (1935); Feigl, p. 124.* Recomm. (*I. C.*).

SODIUM ALIZARIN SULFONATE (ALIZARIN S), in aq. soln., gives a violet-red color with Zr. The reagt. should be added to a neutral test soln. which is then boiled and acidified with a little dil. HCl. The colors given by Al, Th, Be, and Ti salts disappear under these conditions leaving only the Zr. F, PO_4, SO_4 ions intfr. Cf. de Boer, *Chem. Weekblad* **21,** *404 (1924); Feigl, p. 125;* F. Pavelka, *Mikrochemie* **8,** *345-51 (1930).* Recomm. (*I. C.*).

CUPFERRON (AMMONIUM NITROSOPHENYLHYDROXYLAMINE) may be used in H_2SO_4 medium for separating Zr from Al, Cr, uranyl, and B; in the absence of many other elements, such as Ti, Th, Ce, Fe, V, Cb, Ta, W, and Si, it may be used directly for gravmtc. detn.; cf. Lundell and Knowles, *Ind. Eng. Chem.* **12,** *344 (1920); J. Am. Chem. Soc.* **42,** *1439 (1920).*

CONCENTRATIONS OF LABORATORY REAGENTS

COMMONLY USED ACIDS AND AMMONIA*

Freshly opened bottles of these reagents are uniformly of the concentrations indicated below. This may not be true of bottles long opened and this is especially true of ammonia which rapidly loses its strength. In preparing volumetric solutions, it is well to be on the safe side and take a little more than the calculated volume of the concentrated reagent, since it is much easier to dilute a concentrated solution than to strengthen one that is too weak. The *5N* solutions present obvious advantages over the usual indefinite dilutions for use as shelf reagents; however, it is not necessary that these shelf reagents be highly accurate.

	HCl	HNO_3	H_2SO_4	NH_4OH	$HC_2H_3O_2$
Mol. wt.	36.46	63.02	98.07	35.04	60.03
Average sp. gr. of conc. reagent	1.19	1.42	1.84	0.90	1.06
Average % present in conc. reagent	36.0	69.5	96.0	58.6	99.5
Grams active ingredient per ml.	0.426	0.985	1.77	0.527	1.055
Normality of conc. reagent	11.7	15.6	36.1	15.1	17.6
Ml. conc. reagent/liter *N* solution	85.5	64.0	27.8	66.5	56.9
Ml. to dilute to 500 cc. for use as shelf reagent (*5N*)	214	160	70	166	143

Routine Normal Solutions †

A concentrated C. P. acid usually comes to the laboratory in a bottle having a label which states: its molecular weight, M; its specific gravity, d; and its percentage assay, p. When such an acid is used in preparing an aqueous solution of desired normality, N, a convenient formula to employ is:

$$V = \frac{100\ MN}{bpd}$$

wherein b is the basicity of the acid and V is the number of milliliters of concentrated acid required for one liter of the dilute solution.

Example.—Acid Sulfuric is dibasic and has the molecular weight 98.08. If the concentrated acid assays 95.5% and has the specific gravity 1.84, the volume required for one liter of a 0.2 normal solution is:

$$V = \frac{100 \times 98.08 \times 0.2}{2 \times 95.5 \times 1.84} = 5.58 \text{ ml.}$$

Such a solution may often be used just as it stands. Where accuracy is required, it is most conveniently standardized by comparison with a high grade Potassium Biphthalate or other primary standard, *q.v.*

† Hague, *Chemist Analyst* 30, No. 1, p. 21 (1941); reprinted by permission of J. T. Baker Chemical Co.

LABORATORY SOLUTIONS

General Reagents and Special Solutions

Unless otherwise stated, the term *g per liter* signifies grams of the formula indicated dissolved in water and made up to a liter of solution. See also *Standard Volumetric Solutions.*

Acetic acid, $HC_2H_3O_2$—6 *N*: 350 cc glacial acetic acid per liter.

Alcohol, amyl, $C_5H_{11}OH$: use as purchased.

Alcohol, ethyl, C_2H_5OH; 95% alcohol, as purchased.

Aluminon (qualitative test for aluminum). The reagent consists of 0.1% solution of the ammonium salt of aurin tricarboxylic acid. A bright red precipitate, persisting in alkaline solution, indicates aluminum. See special table: *Organic Reagents for Inorganic Analysis.*

Aluminum chloride, $AlCl_3$—0.5 *N*: 22 g per liter.

Aluminum nitrate, $Al(NO_3)_3 \cdot 7.5H_2O$ —0.5 *N*: 58 g per liter.

Aluminum sulfate, $Al_2(SO_4)_3 \cdot 18H_2O$ —0.5 *N*: 55 g per liter.

Ammonium acetate, $NH_4C_2H_3O_2$— 3 *N*: 231 g per liter.

Ammonium carbonate, $(NH_4)_2CO_3 \cdot H_2O$—3 *N*: 171 g per liter; for the anhydrous salt: 144 g per liter.

Ammonium chloride, NH_4Cl—3 *N*: 161 g per liter.

Ammonium hydroxide, NH_4OH— 15 *N*: the concentrated solution which contains 28% NH_3; for 6 *N*: 400 cc per liter.

Ammonium molybdate, $(NH_4)_2MoO_4$—*N*: dissolve 88.3 g of solid $(NH_4)_6Mo_7O_{24} \cdot 4H_2O$ in 100 cc 6 *N* NH_4OH. Add 240 g of solid NH_4NO_3 and dilute to one liter. Another method is to take 72 g of MoO_3, and 130 cc of water and 75 cc of 15 *N* NH_4OH; stir mechanically until nearly all has dissolved, then add it to a solution of 240 cc concentrated HNO_3 and 500 cc of water; stir continuously while solutions are being mixed; allow to stand 3 days, filter, and use the clear filtrate.

Ammonium nitrate, NH_4NO_3—*N*: 80 g per liter.

Ammonium oxalate, $(NH_4)_2C_2O_4 \cdot H_2O$—0.5 *N*: 40 g per liter.

Ammonium polysulfide (yellow ammonium sulfide), $(NH_4)_2S_x$: allow the colorless $(NH_4)_2S$ to stand, or add sulfur.

Ammonium sulfate, $(NH_4)_2SO_4$— 0.5 *N*: 33 g per liter; saturated: dissolve 780 g of $(NH_4)_2SO_4$ in water and make up to a liter.

Ammonium sulfide (colorless), $(NH_4)_2S$—saturated: pass H_2S through 200 cc of concentrated NH_4OH in the cold until no more gas is dissolved, add 200 cc NH_4OH and dilute with water to a liter; the addition of 15 g of sulfur is sufficient to make the polysulfide.

Ammonium thiocyanate: see *Volumetric Solutions.*

Antimony pentachloride, $SbCl_5$— 0.5 *N*: 30 g per liter.

Antimony trichloride, $SbCl_3$—0.5 *N*: 38 g per liter.

Aqua regia: mix 3 parts of concentrated HCl and 1 part of concentrated HNO_3 just before ready to use.

Arsenic acid, $H_3AsO_4 \cdot 0.5H_2O$—0.5 *N* $(= \frac{1}{2}H_3AsO_4 \div 5)$: 15 g per liter.

Arsenous oxide, As_2O_3—0.25 *N*: 8 g per liter for saturation. See also *Volumetric Solutions.*

Aurichloric acid, $HAuCl_4 \cdot 3H_2O$: dissolve in ten parts of water.

Azolitmin solution (indicator): make up a 1% solution of azolitmin by boiling in water for 5 minutes; it may be necessary to add a small amount of NaOH to make the solution neutral.

Bang's reagent (for glucose estimation): dissolve 100 g of K_2CO_3, 66 g of KCl, and 160 g of $KHCO_3$ in the order given in about 700 cc of water at 30°C. Add 4.4 g of copper sulfate and dilute to 1000 cc after the CO_2 is evolved. This solution should be shaken only in such a manner as not to allow the entry of air. After 24 hours 300 cc are diluted to a liter with saturated KCl solution, shaken gently and used after 24 hours; 50 cc ≈ 10 mg glucose.

Barfoed's reagent (test for glucose):

dissolve 66 g of cupric acetate and 10 cc of glacial acetic acid in water and dilute to one liter.

Barium and Calcium chlorides: see *Precipitation reagent.*

Barium chloride, $BaCl_2 \cdot 2H_2O$—0.5 *N*: 61 g per liter.

Barium hydroxide, $Ba(OH)_2 \cdot 8H_2O$—0.2 *N*: 32 g per liter for saturation.

Barium nitrate, $Ba(NO_3)_2$—0.5 *N*: 65 g per liter.

Baudisch's reagent: see *Cupferron.*

Benedict's qualitative reagent (for glucose): dissolve 173 g of sodium citrate and 100 g of anhydrous sodium carbonate in about 600 cc of water, and dilute to 850 cc; dissolve 17.3 g of $CuSO_4 \cdot 5H_2O$ in 100 cc of water and dilute to 150 cc; this solution is added to the citrate-carbonate solution with constant stirring. See also the quantitative reagent below.

Benedict's quantitative reagent (sugar in urine): This solution contains 18 g copper sulfate, 100 g of anhydrous sodium carbonate, 200 g of potassium citrate, 125 g of potassium thiocyanate, and 0.25 g of potassium ferrocyanide per liter; 1 cc of this solution $\approx$0.002 g sugar.

Benzidine hydrochloride solution (for sulfate determination): mix 6.7 g of benzidine $[C_{12}H_8(NH_2)_2]$ or 8.0 g of the hydrochloride $[C_{12}H_8(NH_2)_2 \cdot 2HCl]$ into a paste with 20 cc of water; add 20 cc of HCl (sp. gr. 1.12) and dilute the mixture to one liter with water; each cc of this solution is equivalent to 0.00357 g H_2SO_4.

Bertrand's reagents (glucose estimation): (*a*) 40 *g* of copper sulfate diluted to one liter; (*b*) rochelle salt 200 g, NaOH 150 g and sufficient water to make one liter; (*c*) ferric sulfate 50 g, H_2SO_4 200 g and sufficient water to make one liter; (*d*) $KMnO_4$ 5 g and sufficient water to make one liter.

Bial's reagent (for pentoses): dissolve 1 g of orcinol in 500 cc of 30% HCl to which 30 drops of a 10% ferric chloride solution have been added.

Bismuth chloride, $BiCl_3$—0.5 *N*: 52 g per liter, using 1:5 HCl in place of water.

Bismuth nitrate, $Bi(NO_3)_3 \cdot 5H_2O$—0.25 *N*: 40 g per liter, using 1:5 HNO_3 in place of water.

Bismuth standard solution (quantitative color test for Bi): dissolve 1 g of bismuth in a mixture of 3 cc of concentrated HNO_3 and 2.8 cc of H_2O and make up to 100 cc with glycerol. Also dissolve 5 g of KI in 5 cc of water and make up to 100 cc with glycerol. The two solutions are used together in the colorimetric estimation of Bi.

Boutron-Boudet solution: see *Soap solution.*

Bromine water, saturated solution: to 400 cc of water add 20 cc of bromine; use a glass stopper coated with vaseline.

Brucke's reagent (protein precipitant): dissolve 50 *g* of KI in 500 cc of water, saturate with HgI_2 (about 120 g), and dilute to one liter.

Cadmium chloride, $CdCl_2$—0.5 *N*: 46 g per liter.

Cadmium nitrate, $Cd(NO_3)_2 \cdot 4H_2O$—0.5 *N*: 77 g per liter.

Cadmium sulfate, $CdSO_4 \cdot 4H_2O$—0.5 *N*: 70 g per liter.

Calcium chloride, $CaCl_2 \cdot 6H_2O$—0.5 *N*: 55 *g* per liter.

Calcium hydroxide, $Ca(OH)_2$—0.04 *N*: 10 g per liter for saturation.

Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$—0.5 *N*: 59 *g* per liter.

Calcium sulfate, $CaSO_4 \cdot 2H_2O$—0.03 *N*: mechanically stir 10 g in a liter of water for 3 hours; decant and use the clear liquid.

Carbon disulfide, (CS_2): commercial grade which is colorless.

Chloride reagent: dissolve 1.7 g of $AgNO_3$ and 25 g KNO_3 in water, add 17 cc of concentrated NH_4OH and make up to one liter with water.

Chlorine water, saturated solution: pass chlorine gas into small amounts of water as needed; solutions deteriorate on standing.

Chloroform, $CHCl_3$: commercial grade.

Chloroplatinic acid, $H_2PtCl_6 \cdot 6H_2O$—10% solution: dissolve 1 gram in 9 cc of

water; keep in a dropping bottle.

Chromic chloride, $CrCl_3$—0.5 *N*: 26 g per liter.

Chromic nitrate, $Cr(NO_3)_3$—0.5 *N*: 40 g per liter.

Chromic sulfate, $Cr_2(SO_4)_3 \cdot 18H_2O$—0.5 *N*: 60 g per liter.

Cobaltous nitrate, $Co(NO_3)_2 \cdot 6H_2O$—0.5 *N*: 73 g per liter.

Cobaltous sulfate, $CoSO_4 \cdot 7H_2O$—0.5 *N*: 70 g per liter.

Cupferron (iron analysis): dissolve 6 g of ammonium nitrosophenyl-hydroxylamine (cupferron) in water and dilute to 100 cc. This solution is stable for about one week if protected from light. See special table: *Organic Reagents for Inorganic Analysis.*

Cupric chloride, $CuCl_2 \cdot 2H_2O$—0.5 *N*: 43 g per liter.

Cupric nitrate, $Cu(NO_3)_2 \cdot 6H_2O$—0.5 *N*: 74 g per liter.

Cupric sulfate, $CuSO_4 \cdot 5H_2O$—0.5 *N*: 62 g per liter.

Cuprous chloride, CuCl—0.5 *N*: 50 g per liter, using 1:5 HCl in place of water.

Cuprous chloride, acid (for gas analysis, absorption of CO): cover the bottom of a two-liter bottle with a layer of copper oxide ⅜ inch deep, and place a bundle of copper wire an inch thick in the bottle so that it extends from the top to the bottom. Fill the bottle with HCl (sp. gr. 1.10). The bottle is shaken occasionally, and when the solution is colorless or nearly so, it is poured into half-liter bottles containing copper wire. The large bottle may be filled with hydrochloric acid, and by adding the oxide or wire when either is exhausted, a constant supply of the reagent is available.

Cuprous chloride, ammoniacal: this solution is used for the same purpose, and is made in the same manner as the acid cuprous chloride above, except that the acid solution is treated with ammonia until a faint odor of ammonia is perceptible. Copper wire should be kept with the solution as in the acid reagent.

Dimethyl glyoxime, $(CH_3CNOH)_2$—0.01 *N*: 6 g in 500 cc of 95% alcohol.

See special table: *Organic Reagents for Inorganic Analysis.*

Esbach's reagent (estimation of proteins): dissolve 10 g of picric acid and 20 g of citric acid in water and dilute to one liter.

Eschka's Mixture (sulfur in coal): mix 2 parts of porous calcined MgO with 1 part of anhydrous Na_2CO_3; not a solution but a dry mixture.

Ether, $(C_2H_5)_2O$—use commercial grade.

Fehling's solution (sugar detection and estimation): (*a*) Copper sulfate solution: dissolve 34.639 g of $CuSO_4 \cdot 5H_2O$ in water and dilute to 500 cc. (*b*) Alkaline tartrate solution: dissolve 173 g of rochelle salts ($KNaC_4H_4O_6 \cdot 4H_2O$) and 125 g of KOH in water and dilute to 500 cc. Equal volumes of the two solutions are mixed just prior to use. The Methods of the Assoc. of Official Agricultural Chemists give 50 g of NaOH in place of the 125 g KOH.

Ferric chloride, $FeCl_3$—0.5 *N*: 27 g per liter.

Ferric nitrate, $Fe(NO_3)_3 \cdot 9H_2O$—0.5 *N*: 67 g per liter.

Ferrous ammonium sulfate, Mohr's salt, $FeSO_4 \cdot (NH_4)_2SO_4 \cdot 6H_2O$—0.5 *N*: 98 g per liter. See also *Volumetric Solutions.*

Ferrous sulfate, $FeSO_4 \cdot 7H_2O$—0.5 *N*: 80 g per liter; add a few drops of H_2SO_4.

Folin's mixture (for uric acid): dissolve 500 g of ammonium sulfate, 5 g of uranium acetate, and 6 cc of glacial acetic acid, in 650 cc of water. The volume is about a liter.

Formal or Formalin: use the commercial 40% solution of formaldehyde.

Froehde's reagent (gives characteristic colorations with certain alkaloids and glucosides): dissolve 0.01 g of sodium molybdate in 1 cc of concentrated H_2SO_4; use only a freshly prepared solution.

Glyoxylic acid solution (protein detection): cover 10 g of magnesium powder with water, and add slowly 250 cc of a saturated oxalic acid solution, keeping the mixture cool; filter off the magnesium oxalate, acidify the filtrate with acetic

acid and make up to a liter with water.

Guaiacum tincture: dissolve 1 g of guaiacum in 100 cc of alcohol.

Gunzberg's reagent (detection of HCl in gastric juice): dissolve 4 g of phloroglucinol and 2 g of vanillin in 100 cc of absolute alcohol; use only a freshly prepared solution.

Hager's reagent (for alkaloids): this reagent is a saturated solution of picric acid in water.

Hanus solution (for determination of iodine number): dissolve 13.2 g of iodine in a liter of glacial acetic acid that will not reduce chromic acid; add sufficient bromine to double the halogen content determined by titration (3 cc is about the right amount). The iodine may be dissolved with the aid of heat, but the solution must be cold when the bromine is added.

Hydriodic acid, HI—0.5 *N*: 64 g per liter.

Hydrobromic acid, HBr—0.5 *N*: 40 g per liter.

Hydrochloric acid, HCl—5 *N*: 182 g per liter; sp. gr. 1.084. See also *Volumetric Solutions.*

Hydrofluoric acid, H_2F_2—48% solution: use as purchased, and keep in the special container.

Hydrogen peroxide, H_2O_2—3% solution: use as purchased.

Hydrogen sulfide, H_2S: prepare a saturated aqueous solution.

Iodic acid, HIO_3—0.5 *N* ($HIO_3/12$): 15 g per liter.

Iodine: see *Tincture of iodine*; see also *Volumetric Solutions.*

Litmus solution (indicator): powder the litmus and make up a 2% solution, boiling for 5 minutes.

Lead acetate, $Pb(C_2H_3O_2)_2 \cdot 3H_2O$—0.5 *N*: 95 g per liter.

Lead chloride, $PbCl_2$—saturated solution is 1/7 *N*.

Lead nitrate, $Pb(NO_3)_2$—0.5 *N*: 83 g per liter.

Lime water: see *calcium hydroxide.*

Magnesia mixture: 100 g of $MgSO_4$, 200 g of NH_4Cl, 400 cc of NH_4OH, 800 cc of water; each cc ≈ 0.01 g phosphorus (P).

Magnesium chloride, $MgCl_2 \cdot 6H_2O$—0.5 *N*: 50 g per liter.

Magnesium nitrate, $Mg(NO_3)_2 \cdot 6H_2O$—0.5 *N*: 64 g per liter.

Magnesium sulfate, epsom salts, $MgSO_4 \cdot 7H_2O$—0.5 *N*: 62 g per liter; saturated solution: dissolve 600 g of the salt in water and dilute to one liter.

Manganous chloride, $MnCl_2 \cdot 4H_2O$—0.5 *N*: 50 g per liter.

Manganous nitrate, $Mn(NO_3)_2 \cdot 6H_2O$—0.5 *N*: 72 g per liter.

Manganous sulfate, $MnSO_4 \cdot 7H_2O$—0.5 *N*: 69 g per liter.

Marme's reagent (gives yellowish-white precipitate with salts of alkaloids): saturate a boiling solution of 4 parts of KI in 12 parts of water with CdI_2; then add an equal volume of cold saturated KI solution.

Marquis reagent (gives a purple-red coloration, then violet, then blue with morphine, codeine, dionine, and heroine): mix 3 cc of concentrated H_2SO_4 with 3 drops of a 35% formaldehyde solution.

Mayer's reagent (gives white precipitate with most alkaloids in a slightly acid solution): dissolve 13.55 g of $HgCl_2$ and 50 g of KI in a liter of water.

Mercuric chloride, $HgCl_2$—0.5 *N*: 68 g per liter.

Mercuric nitrate, $Hg(NO_3)_2$—0.5 *N*: 81 g per liter.

Mercuric sulfate, $HgSO_4$—0.5 *N*: 74 g per liter.

Mercurous nitrate, $HgNO_3$: mix 1 part of $HgNO_3$, 20 parts of H_2O, and 1 part of HNO_3.

Methyl orange (indicator): dissolve 1 g of methyl orange in a liter of water.

Methyl red (indicator): dissolve 2 g of methyl red in a liter of alcohol. See also special section on *Acid-Base Indicators.*

Millon's reagent (gives a red precipitate with certain proteins and with

LABORATORY SOLUTIONS

various phenols): dissolve 1 part of mercury in 1 part of HNO_3 (sp. gr. 1.40) with gentle heating, then add 2 parts of water; a few crystals of KNO_3 help to maintain the strength of the reagent.

Mohr's salt: see ferrous ammonium sulfate.

α-Naphthol solution: dissolve 144 g of α-naphthol in enough alcohol to make a liter of solution.

Nessler's reagent (for free ammonia): dissolve 50 g of KI in the least possible amount of cold water; add a saturated solution of $HgCl_2$ until a very slight excess is indicated; add 400 cc of a 50% solution of KOH; allow to settle, make up to a liter with water, and decant.

Nickel chloride, $NiCl_2 \cdot 6H_2O$—0.5 *N*: 59 g per liter.

Nickel nitrate, $Ni(NO_3)_2 \cdot 6H_2O$—0.5 *N*: 73 g per liter.

Nickel sulfate, $NiSO_4 \cdot 6H_2O$—0.5 *N*: 66 g per liter.

Nitric acid, HNO_3—5 *N*: 315 g per liter; sp. gr. 1.165. See also *Volumetric Solutions.*

Nitrohydrochloric acid: see *aqua regia.*

Nitroso-β-naphthol, $HOC_{10}H_6NO$—saturated solution: saturate 100 cc of 50% acetic acid with the solid.

Nylander's solution (detection of glucose): dissolve 40 g of rochelle salt and 20 g of bismuth subnitrate in 1000 cc of an 8% NaOH solution.

Obermayer's reagent (detection of indoxyl in urine): dissolve 4 g of $FeCl_3$ in a liter of concentrated HCl.

Oxalic acid, $H_2C_2O_4 \cdot 2H_2O$: dissolve in ten parts of water. See also *Volumetric Solutions.*

Pavy's solution (estimation of glucose): mix 120 cc of Fehling's solution and 300 cc of ammonium hydroxide (sp. gr. 0.88), and dilute to a liter with water.

Perchloric acid, $HClO_3$—60%: use as purchased.

Phenol solution: dissolve 20 g of phenol (carbolic acid) in a liter of water.

Phenolphthalein solution (indicator): dissolve 1 g of phenolphthalein in 50 cc of alcohol and add 50 cc of water. See also special section on *Acid-Base Indicators.*

Phenol sulfonic acid (determination of nitrogen as nitrate; water analysis for nitrate): dissolve 25 grams of pure, white phenol in 150 cc of pure concentrated H_2SO_4, add 75 cc of fuming H_2SO_4 (15% SO_3), stir well and heat for two hours at 100°C.

Phosphoric acid, *ortho,* H_3PO_4—0.5 *N*: 16 g per liter.

Potassium acid antimonate, KH_2SbO_4—0.1 *N*: boil 23 g of the salt with 950 cc of water for 5 minutes, cool rapidly and add 35 cc of 6 *N* KOH; allow to stand for one day, filter, dilute filtrate to a liter.

Potassium arsenate, K_3AsO_4—0.5 *N* ($K_3AsO_4/10$): 26 g per liter.

Potassium arsenite, $KAsO_2$—0.5 *N* ($KAsO_2/6$): 24 g per liter.

Potassium bromate, $KBrO_3$—0.5 *N* ($KBrO_3/12$): 14 g per liter.

Potassium bromide, KBr—0.5 *N*: 60 g per liter.

Potassium carbonate, K_2CO_3—3 *N*: 207 g per liter.

Potassium chloride, KCl—0.5 *N*: 37 g per liter.

Potassium chromate, K_2CrO_4—0.5 *N*: 49 g per liter.

Potassium cyanide, KCN—0.5 *N*: 33 g per liter. See also *Volumetric Solutions.*

Potassium dichromate, $K_2Cr_2O_7$—0.5 *N* ($K_2Cr_2O_7/8$): 38 g per liter. See also *Volumetric Solutions.*

Potassium ferricyanide, $K_3Fe(CN)_6$—0.5 *N*: 55 g per liter.

Potassium ferrocyanide, $K_4Fe(CN)_6 \cdot 3H_2O$—0.5 *N*: 53 g per liter.

Potassium hydroxide, KOH—5 *N*: 312 g per liter. See also *Volumetric Solutions.*

Potassium iodate, KIO_3—0.5 *N* ($KIO_3/12$): 18 g per liter. See also *Volumetric Solutions.*

Potassium iodide, KI—0.5 *N*: 83 g per liter.

LABORATORY SOLUTIONS

Potassium nitrate, KNO_3—0.5 *N*: 50 g per liter.

Potassium nitrite, KNO_2—6 *N*: 510 g per liter.

Potassium permanganate, $KMnO_4$—0.5 *N* ($KMnO_4/10$): 16 g per liter. See also *Volumetric Solutions.*

Potassium pyrogallate (oxygen in gas ananlysis): weigh out 5 g of pyrogallol (pyrogallic acid), and pour upon it 100 cc of a KOH solution. If the gas contains less than 28% of oxygen, the KOH solution should be 500 g KOH in a liter of water; if there is more than 28% of oxygen in the gas, the KOH solution should be 120 g of KOH in 100 cc of water.

Potassium sulfate, K_2SO_4—0.5 *N*: 44 g per liter.

Potassium thiocyanate, KCNS—0.5 *N*: 49 g per liter.

Precipitating reagent (for group II, anions): dissolve 61 g of $BaCl_2 \cdot 2H_2O$ and 52 g of $CaCl_2 \cdot 6H_2O$ in water and dilute to one liter. If the solution becomes turbid, filter and use filtrate.

Scheibler's reagent (precipitates alkaloids, albumoses and peptones): dissolve sodium tungstate in boiling water containing half its weight of phosphoric acid (sp. gr. 1.13); on evaporation of this solution, crystals of phosphotungstic acid are obtained. A 10% solution of phosphotungstic acid in water constitutes the reagent.

Schweitzer's reagent (dissolves cotton, linen, and silk, but not wool): add NH_4Cl and NaOH to a solution of copper sulfate. The blue precipitate is filtered off, washed, pressed, and dissolved in ammonia (sp. gr. 0.92).

Silver nitrate, $AgNO_3$—0.25 *N*: 43 g per liter. See also *Volumetric Solutions.*

Silver sulfate, Ag_2SO_4—*N*/13 (saturated solution): stir mechanically 10 g of the salt in a liter of water for 3 hours; decant and use the clear liquid.

Soap solution (for hardness in water): (*a*) *Clark's or A.P.H.A. Stand. Methods*—prepare stock solution of 100 g of pure powdered castile soap in a liter of 80% ethyl alcohol; allow to stand over night and decant. Titrate against $CaCl_2$ solution (0.5 g $CaCO_3$ dissolved in a concentrated HCl, neutralized with NH_4OH to slight alkalinity using litmus as the indicator, make up to 500 cc; 1 cc of this solution is equivalent to 1 mg $CaCO_3$) and dilute with 80% alcohol until 1 cc of the resulting solution is equivalent to 1 cc of the standard $CaCl_2$ making due allowance for the lather factor (the lather factor is that amount of standard soap solution required to produce a permanent lather in a 50 cc portion of distilled water). One cc of this solution after subtracting the lather factor is equivalent to 1 mg of $CaCO_3$. (*b*) *Boutron-Boudet*—dissolve 100 g of pure castile soap in about 2500 cc of 56% ethyl alcohol and adjust so that 2.4 cc will give a permanent lather with 40 cc of a solution containing 0.59 g $Ba(NO_3)_2$ per liter of water; 2.4 cc of this solution is equivalent to 22 French degrees or 220 parts per million of hardness (as $CaCO_3$) on a 40 cc sample of water.

Sodium acetate, $NaC_2H_3O_2 \cdot 3H_2O$: dissolve 1 part of the salt in 10 parts of water.

Sodium acetate, acid: dissolve 100 g of sodium acetate and 30 cc of glacial acetic acid in water and dilute to one liter.

Sodium bismuthate (oxidation of manganese): heat 20 parts of NaOH nearly to redness in an iron or nickel crucible, and add slowly 10 parts of basic bismuth nitrate which has been previously dried. Add 2 parts of sodium peroxide, and pour the brownish-yellow fused mass on an iron plate to cool. When cold break up in a mortar, extract with water, and collect on an asbestos filter.

Sodium carbonate, Na_2CO_3—3 *N*: 159 g per liter; one part Na_2CO_3, or 2.7 parts of the crystalline $Na_2CO_3 \cdot 10H_2O$ in 5 parts of water.

Sodium chloride, NaCl—0.5 *N*: 29 g per liter. See also *Volumetric Solutions.*

Sodium chloroplatinite, Na_2PtCl_4: dissolve 1 part of the salt in 12 parts of water.

Sodium cobaltinitrite, $Na_3Co(NO_2)_6$—0.3 *N*: dissolve 230 g of $NaNO_2$ in 500 cc of water, add 160 cc of 6 *N* acetic acid

LABORATORY SOLUTIONS

and 35 g of $Co(NO_3)_2 \cdot 6H_2O$. Allow to stand one day, filter, and dilute the filtrate to a liter.

Sodium hydrogen phosphate, $Na_2HPO_4 \cdot 12H_2O$—0.5 *N*: 60 g per liter.

Sodium hydroxide, NaOH—5 *N*: 220 g per liter. See also *Volumetric Solutions*.

Sodium hydroxide, alcoholic: dissolve 20 g of NaOH in alcohol and dilute to one liter with alcohol.

Sodium hypobromite: dissolve 100 g of NaOH in 250 cc of water and add 25 cc of bromine.

Sodium nitrate, $NaNO_3$—0.5 *N*: 43 g per liter.

Sodium nitroprusside (for sulfur detection): dissolve about one gram of sodium nitroprusside in 10 cc of water; as the solution deteriorates on standing, only freshly prepared solutions should be used. This compound is also called sodium nitroferricyanide and has the formula $Na_2Fe(NO)(CN)_5 \cdot 2H_2O$.

Sodium polysulfide, Na_2S_x: dissolve 480 g of $Na_2S \cdot 9H_2O$ in 500 cc of water, add 40 g of NaOH and 18 g of sulfur, stir mechanically and dilute to one liter with water.

Sodium sulfate, Na_2SO_4—0.5 *N*: 35 g per liter.

Sodium sulfide, Na_2S; saturate NaOH solution with H_2S, then add as much NaOH as was used in the original solution.

Sodium sulfite, $Na_2SO_3 \cdot 7H_2O$—0.5 *N*: 63 g per liter.

Sodium sulfite, acid (saturated): dissolve 600 g of $NaHSO_3$ in water and dilute to one liter; for the preparation of addition compounds with aldehydes and ketones: prepare a saturated solution of sodium carbonate in water and saturate with sulfur dioxide.

Sodium tartrate, acid, $NaHC_4H_4O_6$: dissolve 1 part of the salt in 10 parts of water.

Sodium thiosulfate, $Na_2S_2O_3 \cdot 5H_2O$: one part of the salt in 40 parts of water. See also *Volumetric Solutions*.

Sonnenschein's reagent (alkaloid detection): a nitric acid solution of ammonium molybdate is treated with phosphoric acid. The precipitate so produced is washed and boiled with aqua regia until the ammonium salt is decomposed. The solution is evaporated to dryness and the residue is dissolved in 10% HNO_3.

Stannic chloride, $SnCl_4$—0.5 *N*: 33 g per liter.

Stannous chloride, $SnCl_2 \cdot 2H_2O$—0.5 *N*: 56 g per liter. The water should be acid with HCl and some metallic tin should be kept in the bottle.

Starch solution (iodine indicator): dissolve 5 g of soluble starch in cold water, pour the solution into 2 liters of water and boil for a few minutes. Keep in a glass-stoppered bottle.

Starch solution (other than soluble): make a thin paste of the starch with cold water, then stir in 200 times its weight of boiling water, and boil for a few minutes. A few drops of chloroform added to the solution acts as a preservative.

Stoke's reagent: dissolve 30 g of ferrous sulfate and 20 g of tartaric acid in water and dilute to one liter. When required for use, add strong ammonia until the precipitate first formed is dissolved.

Strontium chloride, $SrCl_2 \cdot 6H_2O$—0.5 *N*: 67 g per liter.

Strontium nitrate, $Sr(NO_3)_2$—0.5 *N*: 53 g per liter.

Strontium sulfate, $SrSO_4$: prepare a saturated solution.

Sulfanilic acid (for detection of nitrites): dissolve 8 g of sulfanilic acid in one liter of acetic acid (sp. gr. 1.04).

Sulfuric acid, H_2SO_4—5 *N*: 245 g per liter, sp. gr. 1.153. See also *Volumetric Solutions*.

Sulfurous acid, H_2SO_3: saturate water with sulfur dioxide.

Tartaric acid, $H_2C_4H_4O_6$: dissolve one part of the acid in 3 parts of water; for a saturated solution dissolve 750 g of tartaric acid in water and dilute to one liter.

Tannic acid: dissolve one g of tannic

acid in one cc of alcohol and make up to 10 cc with water.

Tincture of iodine (antiseptic): add 70 g of iodine and 50 g of KI to 50 cc of water; make up to one liter with alcohol.

***o*-Tolidine solution** (for residual chlorine in water analysis): dissolve 1 g of pulverized *o*-tolidine, m.p. 129°C., in one liter of dilute hydrochloric acid (100 cc conc. HCl diluted to one liter).

Trichloroacetic acid: dissolve 100 g of the acid in water and dilute to one liter.

Turmeric paper (gives a rose-brown coloration with boric acid): wash the ground root of turmeric with water and discard the washings. Digest with alcohol and filter, using the clear filtrate to impregnate white, unsized paper, which is then dried.

Uffelmann's reagent (gives a yellow coloration in the presence of lactic acid): add a ferric chloride solution to a 2% phenol solution until the solution becomes violet in color.

Wagner's solution (phosphate rock analysis): dissolve 25 g of citric acid and one g of salicylic acid in water, and make up to one liter. Twenty-five to 50 cc of this reagent prevents precipitation of iron and aluminum.

Wijs solution (for iodine number): dissolve 13 g of resublimed iodine in one liter of glacial acetic acid (99.5%), and pass in washed and dried (over or through H_2SO_4) chlorine gas until the original thio titration of the solution is not quite doubled. There should be only a slight excess of iodine and no excess of chlorine. Preserve the solution in amber colored bottles sealed with paraffin. Do not use the solution after it has been prepared for more than 30 days.

Xylene cyanole-methyl orange indicator, Schoepfle modification (for partially color blind operators): dissolve 0.75 g of xylene cyanole FF (Eastman No. T 1579) and 1.50 g methyl orange in one liter of water.

Zinc chloride, $ZnCl_2$—0.5 *N*: 34 g per liter.

Zinc nitrate, $Zn(NO_3)_2 \cdot 6H_2O$—0.5 *N*: 74 g per liter.

Zinc sulfate, $ZnSO_4 \cdot 7H_2O$—0.5 *N*: 72 g per liter.

TRUE CAPACITY OF GLASS VESSELS

Based on 25×10^{-6} as the coefficient of cubical expansion of glass.

The capacity of a vessel may be obtained by determining the weight of a contained liquid. The true capacity of glass vessels when their contents of water or mercury are weighed in air with brass weights can be found by means of the following equation:

$$V t^\circ = W t^\circ \times C \text{ at } t^\circ$$

where Vt° is the true volume of the vessel at t° when it contains W grams of water or mercury at t°. Thus, if the contents of a flask filled with water weigh 100 grams at 15°, then the true volume of the flask at 15° is 100×1.001935, or 100.1935 cc.

If it is desired to find the true volume of a flask at 18° or at 25° when its contents are weighed at some other temperature, t°, the equation becomes $V_{18}^\circ = W t^\circ \times C_{18}^\circ$ at t°, or $V_{25}^\circ = W t^\circ \times C_{25}^\circ$ at t°. Thus, if the water in a flask weighed 100 grams at 15°, the true volume of the flask at 25° is 100×1.002186, or 100.2186 cc.

STANDARD VOLUMETRIC (TITRIMETRIC) SOLUTIONS

International Atomic Weights of 1941 *.

Alkaline arsenite, 0.1N. As^{3} to As^{5}. Dissolve 4.9455 g. of sublimed As_2O_3 in a concentrated solution of NaOH, being careful not to warm the solution over 60°C. Add this mixture to 100 ml. of a saturated $NaHCO_3$ solution, and dilute to one liter. Standardize against a standard iodine solution using a starch indicator. One ml. of 0.1N arsenite is equal to 0.012692 g. of iodine.

Ammonium thiocyanate, 0.1N. Dissolve 7.6118 g. of NH_4CNS in water and dilute to a liter. Standardize against standard silver nitrate solution, using a ferric alum indicator.

Ferrous ammonium sulfate (Mohr's salt), 0.1N. Fe^{2} to Fe^{3}. Dissolve 39.2146 g. of $FeSo_4 \cdot (NH_4)_2SO_4 \cdot 6H_2O$ in water and dilute to a liter. Standardize against standard potassium permanganate or dichromate solution.

Hydrochloric acid, HCl. This acid may be standardized by the method of Hulett and Bonner as modified by Foulk and Hollingsworth (J. Am. Chem. Soc. 31, 390, (1909); *ibid.* 45, 1227 (1923)). For the preparation of a standard acid, HCl of approximately 1.10 density (as determined with a hydrometer) should be distilled at the rate of 3 to 4 ml. a minute. After three-fourths of the liquid has distilled the portion to be used as constant-boiling mixture should be collected. Distillation must, however, not be carried so far that less than 50 to 60 ml. of liquid remains in the flask. This acid is of constant composition, is not noticeably hygroscopic or volatile, and can be accurately weighed into a small flask, using a capillary pipette to obtain the exact weight desired. The preceding table by Foulk and Hollingsworth is based upon the atomic weights Ag = 107.88; Cl = 35.46; H = 1.008. Thus, to make 0.1N acid when the barometer reads 760 mm weigh out 18.0193 g. of distillate and dilute to a liter. For N acid use 180.193 g. Another method of making N acid is to mix one volume of the concentrated acid with 11 volumes of water and standardize by the precipitation of AgCl. For 0.1N acid use a 1 to 110 mixture.

Barometer Pressure, mm of Hg	%HCl Vacuum weight basis	Grams (air-wt.) of const.-boiling distillate that contains 1 mole (vac.) of HCl
770	20.197	180.407
760	20.221	180.193
750	20.245	179.979
740	20.269	179.766
730	20.293	179.555

Iodine, 0.1N. I^{0} to I^{-1}. Dissolve 12.692 g. of resublimed iodine in a saturated solution of 16 g. of KI, and dilute to a liter. This solution can be used as a primary standard if the weighing is carefully done, or it can be checked against a known sodium thiosulfate solution, using a starch indicator.

Nitric acid, N. Normal acid contains 63.016 g. of HNO_3 per liter. Use a colorless acid, which can be made from the yellow acid by adding water and boiling. About 65 ml. of 1.42 sp. gr. acid diluted to a liter is nearly normal. Standardize by titration with a standard alkali.

Oxalic acid, N. Normal acid should contain 63.034 g. of $H_2C_2O_4 \cdot 2H_2O$ (or 45.018 g. of the anhydrous acid) per liter. Because of the uncertainty in the amount of water of crystallization oxalic acid solutions must be checked against a known alkali, using a phenolphthalein indicator. This acid is not commonly used in volumetric work, as the weaker solutions are unstable, and the more concentrated solutions tend to give a precipitate if they are allowed to become too cold.

Potassium cyanide, for nickel titration, 0.1N = 0.4 × KCN = 26.0456 g. per liter. To make up this solution dissolve 26.0456 g. of KCN in water, add 10 g. of KOH to prevent hydrolysis, and dilute to a liter. For silver titration, 0.1N = 0.2 × KCN. In this case use 13.0228 g. of KCN and 5 g. of KOH.

Potassium dichromate, 0.1N. Cr^{6} to Cr^{3}. Weigh out 4.9035 g. of $K_2Cr_2O_7$ that has been oven-dried and cooled in a desiccator, and dilute with water to a liter. This 0.1N solution may be used in standardizing a sodium thiosulfate solution. Before using in an iron analysis,

**For the most recent atomic weights see inside of back cover.*

the dichromate should be checked against a known iron sample. In this titration an external indicator of $K_3Fe(CN)_6$ is used.

Potassium hydroxide, 0.1N. This solution should contain 5.6104 g. of KOH per liter, but it is best to dissolve about 7 g. in a half-liter of water, add enough $BaCl_2$ to precipitate any carbonate that may be present, allow the $BaCO_3$ to settle, filter into a liter flask and dilute to the mark with CO_2-free water. Standardize with succinic, sulfuric, or hydrochloric acid, using a phenolphthalein or methyl orange indicator. The solution made up in this manner is slightly more than 0.1N, but it can easily be adjusted after an acid titration. Alkali solutions must be protected from air by having the bottle stoppers coated with vaseline.

Potassium iodate, 0.1N. I^{+5} to I^{-1}. Dry the KIO_3 in an oven at 120°C., cool in a desiccator, and weigh out exactly 3.567 g. of KIO_3 and about 15 g. of KI, dissolve in distilled water and dilute to a liter. This solution can be used as a standard if the iodate is pure and is carefully weighed.

Potassium permanganate, 0.1N. Mn^7 to Mn^2. A tenth normal solution contains 3.1605 g. of $KMnO_4$ per liter. Dissolve a little more than the calculated amount (about 3.3 g.) in a liter of distilled water. Allow this to stand for 2 or 3 days, then siphon it carefully through clean glass tubes into the container in which it is to be kept, discarding the first 25 ml. and allowing the last inch of liquid to remain in the bottle. In this way any dust or reducing substance in the water is oxidized, and the MnO_2 so formed is left out of the final solution. Permanganate solutions should never be allowed to touch rubber, filter paper, or any other organic matter. To standardize the $KMnO_4$, weigh out several samples of about 0.3 g. of pure, dry sodium oxalate into Erlenmeyer flasks, add 150 ml. of distilled water and 4 ml. of concentrated H_2SO_4, and heat nearly to boiling. When all has been dissolved, run in the $KMnO_4$ from a burette not faster than 15 ml. per minute. The last ml. should be added drop by drop until a faint, permanent pink color is obtained. The temperature should be kept around 70°C. throughout this titration. Each ml. of 0.1N $KMnO_4$ is equal to 0.0067007 g. of sodium oxalate. The equation is $2KMnO_4 + 5Na_2C_2O_4 + 8H_2SO_4 \rightarrow K_2SO_4 + 2MnSO_4 + 5Na_2SO_4 + 10\ CO_2 + 8H_2O$.

Silver nitrate, 0.1N. A tenth normal solution contains 16.9888 g. of $AgNO_3$ per liter. Weigh out about 17.1 g. of $AgNO_3$ and dissolve in a liter of distilled water. Standardize against a standard NaCl solution by the method of Mohr or Volhard, or by precipitating and weighing AgCl.

Sodium chloride, 0.1N. This solution contains 5.8454 g. of NaCl per liter. If the salt is dried, weighed, and diluted to a definite volume it may be used as a primary standard.

Sodium hydroxide, 0.1N. This solution contains 4.0005 g. of NaOH per liter. It is prepared in the same manner as the potassium hydroxide solution, using about 6 g. for the 0.1N solution, and about 42 g. for the normal solution.

Sodium thiosulfate, 0.1N. This solution contains 24.8194 g. per liter. Weigh out 25 g. of $Na_2S_2O_3 \cdot 5H_2O$ and dilute to a liter. Let stand for two weeks, and if any sulfur has settled decant the clear liquid. Standardize against resublimed iodine in the following manner: weigh out 0.5 g. of pure iodine and dissolve in a solution of 3 g. of KI dissolved in as little water as possible. Dilute to about 200 ml. and titrate with the thiosulfate using a starch indicator. Each ml. of 0.1N thio is equal to 0.012692 g. of iodine.

Succinic acid, 0.1N. This acid can be used as a primary standard if it is carefully weighed and diluted to a definite volume. Dry about 6 g. of $H_2C_4H_4O_4$ in an oven at 105°C. and cool in a desiccator. Weigh out exactly 5.9044 g. and dilute to a liter. This solution is exactly 0.1N.

Sulfuric acid, N. This solution contains 49.038 g. of H_2SO_4 per liter. The 0.1N. solution contains 4.9038 g. per liter. Pour 30 ml. (3 ml. for the 0.1N.) of pure concentrated sulfuric acid of density 1.84 into 3 or 4 volumes of water. This must be done slowly and carefully. Cool the mixture and dilute to a liter. Standardize against a known KOH or NaOH solution, using a phenolphthalein indicator.

A METHOD FOR BALANCING EQUATIONS FOR OXIDATION -REDUCTION REACTIONS

Reprinted by permission, from *Outline of the Methods of Qualitative Chemical Analysis*, 13th Edition (1928), by R. J. Carney; copyright 1928 by Geo. Wahr, publisher; Ann Arbor, Mich.

The rule for balancing equations in which oxidation and reduction takes place was originated by O. C. Johnson in 1880 (Chem. News 42, 51). It is an excellent and useful rule if a term such as "oxidation number" is substituted for the term "bond." The oxidation number of an element is often the same number as its valence; in many cases, however, the two numbers are entirely different. The oxidation number of an element is determined by the following simple rules:

(a) Hydrogen has an oxidation number of + 1.

(b) Oxygen has an oxidation number of − 2, except in H_2O_2 and peroxides.

(c) Free elements have an oxidation number of 0.

(d) The sum of the oxidation numbers of the elements in a compound is 0.

Examples: (1) Find the oxidation number of P in H_3PO_4. Three of hydrogen have an oxidation number of + 3, four of oxygen have an oxidation number of − 8, the atom of phosphorus must have an oxidation number of + 5 in order that the sum shall be 0. The valence of phosphorus is also 5.

(2) Find the oxidation number of C in CH_2O. Two of hydrogen have an oxidation number of + 2, one of oxygen has an oxidation number of − 2, therefore the oxidation number of the atom of carbon is 0. The valence of carbon is 4.

(3) Find the oxidation number of As in Ag_3AsO_3. This salt is derived from H_3AsO_3. The rules are applied to this acid.

The total gain in oxidation number for all of the atoms in one molecule of the reducing agent is the number of molecules of the oxidizing agent to be taken; the total loss in oxidation number for all of the atoms in one molecule of the oxidizing agent is the number of molecules of the reducing agent to be taken. After obtaining these two numbers the rest of the equation can be balanced by inspection.

Oxidation equations may be divided into three classes:

(a) in which the oxidizing agent and reducing agent simply oxidizes and reduces;

(b) in which part of the oxidizing agent or reducing agent also enters into combination without being oxidized or reduced;

(c) in which all of the elements oxidized and reduced are present in the same molecule.

Example of (a):

$3\,As_4 + 20\,HNO_3 + 8\,H_2O = 12\,H_3AsO_4 + 20\,NO$. Four atoms of arsenic in metallic arsenic have an oxidation number of 0, in H_3AsO_4, the four atoms of arsenic have an oxidation number of +20; the total gain for the molecule (As_4) is 20, and therefore 20 of HNO_3 are taken. One atom of nitrogen in HNO_3 has an oxidation number of + 5, in NO it has an oxidation number of +2; the total loss for the molecule (HNO_3) is 3, and therefore 3 of As_4 are taken.

Example of (b):

$3\,Cu + 8\,HNO_3 = 3\,Cu(NO_3)_2 + 2\,NO + 4\,H_2O$. One of Cu gains 2 and therefore 2 of HNO_3 are required to oxidize it. One of N loses 3 and therefore 3 of Cu are taken. This indicates that 3 of $Cu(NO_3)_2$ and 2 of NO are formed. Six of HNO_3 are evidently required to unite with the copper, and these are added to the two required to oxidize it.

Example of (c):

$3\,HClO_3 = HClO_4 + 2\,ClO_2 + H_2O$. The $HClO_3$ should be written twice, considering the one part to be the oxidizer and the other the reducer. $2\,HClO_3$ (oxidizing) $+ HClO_3$ (reducing) $= HClO_4 + 2ClO_2 + H_2O$. The oxidizing $HClO_3$ changes to ClO_2, the reducing to $HClO_4$. On application of the rule, it is found that two molecules of the oxidizing $HClO_3$ are to be taken and this indicates that two molecules of ClO_2 are formed; since it is found that one molecule of the reducing $HClO_3$ is to be taken, one of $HClO_4$ is formed.

It should be kept in mind that more than one element in the same molecule may change in oxidation number.

EQUATIONS AND EQUIVALENTS FOR VOLUMETRIC (TITRIMETRIC) ANALYSIS

Aluminum

(1) $Al_2(SO_4)_3 + 6KOH = 2Al(OH)_3 + 3K_2SO_4$

$$KOH \approx \frac{Al}{3} \approx \frac{Al_2O_3}{6} \approx \frac{Al_2(SO_4)_3}{6}$$

(2) $Al_2(SO_4)_3 + 5KI + KIO_3 + 3H_2O = 2Al(OH)_3 + 3K_2SO_4 + 3I_2$

$$I \approx \frac{Al}{3} \approx \frac{Al_2(SO_4)_3}{6}$$

Antimony

(3) $H_3SbO_4 + 2HI = H_3SbO_3 + H_2O + I_2$

$$I \approx \frac{Sb}{2} \approx \frac{H_3SbO_4}{2}$$

(4) $SbCl_5 + 2KI = SbCl_3 + 2KCl + I_2$

$$I \approx \frac{Sb}{2} \approx \frac{Sb_2O_5}{4}$$

(5) $Sb_2O_5 + 4HI = Sb_2O_3 + 2H_2O + 2I_2$

$$I \approx \frac{Sb}{2} \approx \frac{Sb_2O_5}{4}$$

(6) $Sb_2S_5 + 6HCl = 2SbCl_3 + 2S + 3H_2S$

$$3H_2S + 3I_2 = 6HI + 3S$$

$$I \approx \frac{Sb}{3} \approx \frac{Sb_2S_5}{6}$$

(7) $2H_3SbO_3 + KIO_3 + 2HCl = 2H_3SbO_4 + KCl + ICl + H_2O$

$$\frac{KIO_3}{6} \approx \frac{Sb}{3} \approx \frac{H_3SbO_3}{3}$$

(8) $2NaSbO_3 + 4HI = 2NaSbO_2 + 2H_2O + 2I_2$

$$I \approx \frac{NaSbO_3}{2}$$

(9) $H_3SbO_3 + I_2 + H_2O = H_3SbO_4 + 2HI$

$$I \approx \frac{Sb}{2} \approx \frac{H_3SbO_3}{2}$$

(10) $Sb_2O_3 + 2I_2 + 2H_2O = Sb_2O_5 + 4HI$

$$I \approx \frac{Sb}{2} \approx \frac{Sb_2O_3}{4}$$

EQUATIONS AND EQUIVALENTS FOR TITRIMETRIC ANALYSIS

(11) $SbCl_3+I_2+2HCl=SbCl_5+2HI$

$$I \backsimeq \frac{Sb}{2} \backsimeq \frac{SbCl_3}{2}$$

(12) $Sb_2S_3+6HCl=2SbCl_3+3H_2S$

TITRIMETRIC FACTORS AND THEIR LOGARITHMS

ACIDS*

The following factors are the equivalent of one milliliter of *normal acid*. Where the normality of the solution which is being used is other than normal multiply the factors given in the table below by the normality of the solution employed.

The equivalents of the esters are based on the results of saponification.

The indicators methyl orange and phenolphthalein are indicated by the abbreviations MO and PH respectively.

**For the most recent atomic weights see inside of back cover.

†In alcoholic soln., using methyl red or bromothymol blue as the indicator.

GRAVIMETRIC FACTORS AND THEIR LOGARITHMS

Based on the 1941 International Atomic Weights.*

In the table below the elements are arranged in alphabetical order.

Example:—To convert a given weight of Al_2O_3 to its equivalent of Al multiply by the factor at the right, 0.52914; similarly to convert Al to Al_2O_3, multiply by the factor at the left, 1.8899. For convenience in computation, the corresponding logarithms are given in each case.

Log. of factor −10	Factor		Factor	Log. of factor −10
		ALUMINUM **Al = 26.97**		
9.87485	0.74964	$Al \leftrightarrow Al_4C_3$	1.3340	10.12515

CUPROUS OXIDE AND COPPER EQUIVALENT OF DEXTROSE, INVERT SUGAR, LACTOSE AND MALTOSE *

Method of Munson and Walker, *Jour. Amer. Chem. Soc.* 28, 663, (1906).

Twenty five ml. (25 ml.) of Fehling Solution A and 25 ml. of Fehling Solution B as modified by the Assoc. of Official Agricultural Chemists (for preparation of these solutions see under *Special Reagents and Solutions*) are added to 50 ml. of the sugar solution in a 400 ml. beaker (when a smaller volume of sugar solution must be used, sufficient water must be added to make the final volume of solution 100 ml.) and the mixture heated at such a rate that a boiling temperature is obtained in four minutes and the boiling continued for exactly two minutes longer, keeping the beaker covered with a watch glass throughout the entire time of heating; the mixture is immediately filtered with suction through a Gooch crucible, washing the precipitated cuprous oxide first with water at 60°C., then with 10 ml. of alcohol and finally with 100 ml. of ether; after drying for 30 minutes at 100°C. and cooling in a desiccator it is weighed as cuprous oxide.

(Values in the Table Expressed in Milligrams)

Cuprous Oxide (Cu_2O)	Copper (Cu)	Dextrose (*d*-Glucose)	Invert Sugar	Lactose $C_{12}H_{22}O_{11}+H_2O$	Maltose $C_{12}H_{22}O_{11}+H_2O$

MUNSON-WALKER REDUCING-SUGAR VALUES

Cf. Lester D. Hammond, *Jour. Res. Natl. Bu. Stand. 24, 579 (1940)*.

Sugars of higher purity than those originally used in making up the Munson-Walker determinations having become available, a redetermination of the earlier work has been made by Hammond. To this have been added the values for levulose, as well as the values for an additional sugar mixture containing 0.3 g. of total sugar. This latter mixture extends the adaptability of the method to include such products as simulated molasses, which contain such high percentages of invert sugar in the total sugar present that neither column of sugar-mixture values in the original Munson-Walker table was directly applicable. The invert sugar used in the determination of the values given in the following table were prepared by taking equal weights of crystalline dextrose and levulose. The conditions of the Munson-Walker method [1] were followed, except that the copper was determined electrolytically and the solution was heated by electricity.

The 400 ml. beaker is placed in an electric heater such that the 100 ml. of solution it contains is entirely surrounded by a nest of the resistance wire. The electric current is adjusted so that the solution can be brought to boiling in the 4-minute interval used in the method to within ±5 seconds.

The cuprous oxide is transferred to a Gooch crucible, washed, and then dissolved by the slow dropwise addition of 5 ml. of 1:1 nitric acid. The copper nitrate is received in a 250 ml. beaker, and 10 ml. of 1:1 nitric acid added, as well as about 5 g. of ammonium sulfate. Enough water to cover the cylindrical platinum-gauze electrodes is added, making the total volume of electrolyte about 180 ml. The electrolysis is conducted for about 36 hours [2] at a current density of approximately 0.10 amp./sq. dm.; and upon completion, as indicated by the ferrocyanide test, the electrolyte is displaced with distilled water before breaking the current. The copper deposit is washed with alcohol, dried for 15 minutes at 100°C., cooled in a desiccator, and weighed.[3]

(Values in the Table Expressed in Milligrams) [4]

Copper (Cu)	Cuprous Oxide (Cu_2O)	Dextrose (*d*-Glucose)	Invert Sugar	Invert Sugar and Sucrose			Levulose

34	38.3	16.2	17.3	15.5	15.1	9.0	17.9

[1] See preceding table.

[2] The electrolysis can be completed overnight by using a larger current. Cf. Sherrer, Bell, and Mogerman, *Jour. Res. Natl. Bu. Stand. 22, 697 (1939)*.

[3] In the routine analysis of sugar products, any method of determining copper which is suitable to the products may be used.

[4] The values in the table for concentrations of reducing sugar less than 20 mg are extrapolated and should be used with caution and only for approximate determinations.

REDUCTION VALUES OF GLUCOSE IN BLOOD

Method of Hagedorn and Jensen, *Biochem. Zeit*, 135, 46; 137, 92 (1923).

Required solutions. *Aklaline ferricyanide*, 1.65 g potassium ferricyanide, and 10.6 g anhydrous sodium carbonate in 1000 cc of water; *acetic acid* (3%), 15 g glacial acetic acid in 485 cc of water; *iodide-sulfate*, 5 g potassium iodide, 50 g sodium chloride and 10 g zinc sulfate in sufficient water to make 200 cc of solution; 2.25 g *zinc sulfate* in sufficient water to make 500 cc of solution; standard 0.005 *N sodium thiosulfate*; standard 0.1 *N sodium hydroxide*; starch indicator solution.

Procedure. This method depends upon the reduction of potassium ferricyanide in alkaline solution by the glucose in the blood with subsequent titration of excess unreduced ferricyanide according to the reaction: $2H_3Fe(CN)_6 + 2HI = 2H_4Fe(CN)_6 + I_2$. One cc of 0.1 *N* sodium hydroxide and 5 cc of 0.45% zinc sulfate are mixed in a 15×150 mm test tube and to this is added 0.1 cc of blood from a capillary pipette which is then washed out with the mixture in the test tube; after heating this mixture for three minutes in a boiling water bath, then filtering through cotton into a 30×90 mm test tube and washing the filter with two 3 cc portions of distilled water, 2 cc of alkaline ferricyanide solution is added and the heating continued in the boiling water bath for 15 minutes; after cooling, adding 3 cc of the iodide-sulfate solution and 2 cc of 3% acetic acid solution, it is titrated with 0.005 *N* sodium thiosulfate with starch indicator.

Amount of Glucose in 0.1 cc of Blood Expressed in Milligrams

Methods of Somogyi, *J. Biol. Chem.* 70, 599 (1926).

For 1:10 Blood Filtrate

Required solutions. *Copper reagent*, 6.5 g crystalline copper sulfate, 12 g rochelle salt, 20 g anhydrous sodium carbonate, 10 g potassium iodide, 0.08 g potassium iodate, 18 g potassium oxalate, 25 g sodium bicarbonate and sufficient water to make one liter of solution. *Sulfuric acid*, 5 *N*. Standard sodium thiosulfate, 0.005 *N*.

Procedure. Five cc of the sugar solution (containing between 0.1 and 2.0 milligrams of glucose) is added to 5 cc of copper reagent in a 25×250 mm test tube, then heated for 15 minutes in a boiling water bath; after cooling to 35°C and mixing with 1 cc 5 *N* sulfuric acid, it is titrated two minutes later with 0.005 *N* sodium thiosulfate. A blank titration using 5 cc of water in place of the blood is run simultaneously.

For 1:15 Filtrate

Required solutions. *Sulfuric acid*, 0.067 *N* and 2 *N*. 2.5% *sodium tungstate* solution. *Copper reagent* prepared as described above. Standard *sodium thiosulfate*, 0.005 *N*.

Procedure. Two tenths (0.2) cc of blood is added to 2 cc of 0.067 *N* sulfuric acid in a test tube and the pipette washed several times with the mixture in the test tube; exactly 0.8 cc of 2.5% sodium tungstate is added, the mixture centrifugated and 2 cc of the liquid withdrawn with a pipette filtering the solution through a layer of cotton fastened over the end of the pipette; this 2 cc is added to exactly 2 cc of copper reagent in a 16×150 mm test tube, mixed and heated for 15 minutes in a boiling water bath; after cooling to 35°C, adding 1 cc of 2 *N* sulfuric acid, it is titrated with 0.005 *N* sodium thiosulfate. A blank using 0.2 cc of water in place of the blood is run simultaneously.

SOLUBILITY OF GASES IN WATER

The column headed "α" gives the volume of gas reduced to standard conditions (0°C and 760 mm) dissolved in one volume of water when the pressure of the gas (without the aqueous tension) is 760 mm; this value "α" is the "absorption coefficient." The column headed "l" gives the volume of the gas expressed in cubic centimeters dissolved in one volume of water at a total pressure (partial pressure of the gas plus the aqueous tension at the stated temperature) of 760 mm. The column headed "q" gives the weight of gas in grams dissolved in 100 grams of water at a total pressure (partial pressure of the gas plus the aqueous tension at the stated temperature) of 760 mm.

*Atmospheric Nitrogen containing 98.815% N_2 by volume + 1.185% inert gases.

SOLUBILITY PRODUCT

In a saturated solution of any given salt, the product of the concentrations of the ions which are combining to form the salt, is a constant. If more than one ion of the same kind enters into the formation of one molecule of the compound then the concentration of that ion must be raised to a power equal to the number of such ions entering into one molecule of the compound. The concentrations are expressed as gram molecular concentrations per liter. For example, silver acetate has a solubility of 10.07 grams per liter at 16°C. Its molecular weight is 167 and it is 70.8% ionized. Therefore, its molar concentration would be 10.07/167 and since it is 70.8% ionized, the Ag ion concentration would be $10.07/167 \times 70.8\%$ or 0.0427. Since for each silver ion there is an acetate ion, the acetate ion concentration would be the same as for the silver ion. Hence the solubility product would be $0.0427 \times 0.0427 = 0.00182$ at 16 °C.

GUM AND

The time for evaporation is based upon the time required to completely evaporate 0.5 cc of solvent on filter paper as compared with the corresponding time for ethyl ether which is given a value of 1.

*indicates that dilution causes cloudiness or precipitation.

† Other grades of shellac are less soluble.

The table above shows the volume to which a more concentrated solution must be diluted to obtain the desired more dilute solution. Thus, 100 cc of a solution containing 15% of solute must be diluted to 300 cc to obtain a concentration of 5% and diluted to 150 cc to obtain a concentration of 10%. To prepare 1000 cc of a 5% solution by dilution of a 15% solution: (1000/300) $\times$100 or 333.33 cc of the 15% solution are diluted to 1000 cc.

HYDROMETERS

Various hydrometers and the relation between the various scales.

Alcoholometer. This hydrometer is used in determining the density of aqueous ethyl alcohol solutions; the reading in degrees is numerically the same as the percentage of alcohol by volume. The scale known as *Tralle* gives the precentage by volume. (See also formulas for conversion to percent by weight, percent by volume, and percent proof.) *Wine* and *Must* hydrometer relations are given below.

Ammoniameter. This hydrometer, employed in finding the density of aqueous ammonia solutions, has a scale graduated in equal divisions from 0° to 40°. To convert the reading to specific gravity multiply by 3 and subtract the resulting number from 1000.

Balling Hydrometer. See under **Saccharometer.**

Barkometer or **Barktrometer.** This hydrometer which is used in determining the density of tanning liquors has a scale from 0° to 80° Bk; the number to the right of the decimal point of a specific gravity reading is the corresponding Bk degree; thus, a specific gravity of 1.015 is 15°Bk.

Baumé Hydrometers. For liquids heavier than water.—This hydrometer was originally based on the density of a 10% sodium chloride solution which was given the value of 10° and the density of pure water which was given the value of 0°, the interval between these two values was divided into 10 equal parts. Other reference points have been taken with the result that so much confusion exists that there are about 36 different scales in use, many of which are incorrect. In general a Baumé hydrometer should have inscribed on it the temperature at which it was calibrated and also the temperature of the water used in relating the density to a specific gravity. The following expression gives the relation between the specific gravity and several of the Baumé scales:—

$$\text{Specific gravity} = \frac{m}{m - \text{Baumé}}$$

m = 145 at 60°/60°F (15.56°C) for the American Scale
m = 144 for the old scale used in Holland
m = 146.3 at 15°C for the Gerlach Scale
m = 144.3 at 15°C for the Rational Scale generally used in Germany

See also special table for conversion to density and Twaddell scale.

For liquids lighter than water.—Originally the density of a solution of 1 gram of sodium chloride in 9 grams of water at 12.5°C was given a value of 0°Bé and pure water a value of 10°Bé. The scale between these points was divided into ten equal parts and these divisions were repeated throughout the scale giving a relation which could be expressed by the formula: Specific gravity = 145.88/(135.88+Bé), which is approximately equal to 146/(136+Bé.) Other scales have since come into more general use such as that of the Bu. of Standards in which the specific gravity at 60°/60°F = 140/(130+Bé.) and that of the American Petroleum Institute (A.P.I. Scale) in which the specific gravity at 60°/60°F = 141.5/(131.5+Bé.)

See also special table for conversion to density and Twaddell scale.

Beck's Hydrometer. This hydrometer is graduated to show a reading of 0° in pure water and a reading of 30° in a solution with a specific gravity of 0.850, with equal scale divisions above and below these two points.

Brix Hydrometer. See under Saccharometers.

Cartier's Hydrometer. This hydrometer shows a reading of 22° when immersed in a solution having a density of 22° Baumé but the scale divisions are smaller than on the Baumé hydrometer in the ratio of 16 Cartier to 15 Baumé.

Fatty Oil Hydrometer. The gradu-

ations on this hydrometer are in specific gravity within the range 0.908 to 0.938. The letters on the scale correspond to the specific gravity of the various common oils as follows: *R*, rape; *O*, olive; *A*, almond; *S*, sesame; *HL*, hoof oil; *HP*, hemp; *C*, cotton seed; *L*, linseed. See also Oleometer below.

Lactometers. These hydrometers are used in determining the density of milk. The various scales in common use are the following:

New York Board of Health has a scale graduated into 120 equal parts, 0° being equal to the specific gravity of water and 100° being equal to a specific gravity of 1.029.

Quevenne lactometer is graduated from 15° to 40° corresponding to specific gravities from 1.015 to 1.040.

Soxhlet lactometer has a scale from 25° to 35° corresponding to specific gravities from 1.025 to 1.035 respectively.

Oleometer. A hydrometer for determining the density of vegetable and sperm oils with a scale from 50° to 0° corresponding to specific gravities from 0.870 to 0.970. See also *Fatty Oil* hydrometer above.

Saccharometers. These hydrometers are used in determining the density of sugar solutions. Solutions of the same concentration but of different carbohydrates have very nearly the same specific gravity and in general a concentration of 10 grams of carbohydrate per 100 cc of solution shows a specific gravity of 1.0386. This relation can be expressed as follows:

(a) For concentrations below 12g/100 cc, weight of sugar = density − 1000/3.86

(b) For concentrations above 12g/100 cc, weight of sugar = density − 1000/3.85

The following hydrometers are employed with sugar solutions:

Brix hydrometer is graduated so that the number of degrees is identical with the percentage by weight of cane sugar and is used at the temperature indicated on the hydrometer.

Balling's saccharometer is used in Europe and is practically identical with the Brix hydrometer.

Bates brewers' saccharometer which is used in determining the density of malt worts is graduated so that the divisions express pounds per barrel (32 gallons). The relation between degrees Bates (=b) and degrees Balling (=B) is shown by the following formula: $B = 260b/(360+b)$.

See also below under *Wine and Must*.

Salinometer. This hydrometer, which is used in the pickling and meat packing plants, is graduated to show percentage of saturation of a sodium chloride solution. An aqueous solution is completely saturated when it contains 26.4% pure sodium chloride. The range from 0% to 26.4% is divided into 100 parts, each division therefore representing 1% of saturation. In another type of salinometer, the degrees correspond to percentages of sodium chloride expressed in grams of sodium chloride per 100 cc of water.

Sprayometer (Parrot and Stewart).—This hydrometer which is used in determining the density of *lime sulfur* solutions has two scales; one scale is graduated from 0° to 38° Baumé and the other scale is from 1.000 to 1.350 specific gravity.

Tralle Hydrometer. See *alcoholometer* above.

Twaddell Hydrometer. This hydrometer which is used only for liquids heavier than water, has a scale such that when the reading is multiplied by 5 and added to 1000 the resulting number is the specific gravity with reference to water as 1000. To convert specific gravity at 60°/60°F to Twaddell degrees, take the decimal portion of the specific gravity value and multiply it by 200; thus a specific gravity of $1.032 = 0.032 \times 200 = 6.4°$ Tw. See also special table for conversion to density and Baumé scale.

Wine and Must Hydrometer—This instrument has three scales. One scale shows readings of 0° to 30° Brix for sugar (see Brix hydrometer above); another scale from 0° to 15° Tralle is used for sweet wines to indicate the percentage of alcohol by volume; and a third scale from 0° to 20° Tralle is used for tart wines to indicate the percentage of alcohol by volume.

SPECIFIC GRAVITY CORRECTIONS FOR THE BUOYANT EFFECT OF THE AIR

Determinations made with a pyknometer.

$$D_{vac} = \frac{W_2}{W_1} d - 0.0012 \left(\frac{W_2 d}{W_1} - 1 \right)$$

$$S_{vac} = \frac{W_2}{W_1} - 0.0012 \left(\frac{W_2}{W_1} - 1 \right)$$

Where

D_{vac} = density of the liquid in grams per milliliter at t°C corrected for the buoyant effect of air.

W_1 = weight in air of the water required to fill the pykometer at t°C.

W_2 = weight in air of the liquid required to fill the pyknometer at t°C.

d = density of water in grams per milliliter at t°C.

S_{vac} = specific gravity of the liquid at t°C. referred to water at t°C corrected for the buoyant effect of air.

When the weight of the water is determined at a temperature of t°C, and that of the liquid at a different temperature t', the equations above are modified as follows:

$$D_{vac} = \frac{W_2}{W_1} d - 0.0012 \left(\frac{W_2}{W_1} d - 1 \right) + 0.000026 \, (t' - t^\circ) \left(\frac{W_2}{W_1} d \right)$$

$$S_{vac} = \frac{W_2}{W_1} - 0.0012 \left(\frac{W_2}{W_1} - 1 \right) + 0.000026 \, (t' - t^\circ) \left(\frac{W_2}{W_1} \right)$$

Determinations made with a plummet or sinker.

The equations above may also be used when the density is determined with a plummet or sinker, but in this case

W_1 = weight of the plummet in air minus its weight in water.

W_2 = weight of the plummet in air minus its weight in the liquid.

CONVERSION OF SPECIFIC GRAVITY AT 25°/25° C. TO DENSITY AT ANY TEMPERATURE FROM 0° TO 40° C.

Cf. Dreisbach, *Ind. Eng. Chem., Anal. Ed. 12, 160 (1940).*

Liquids change volume with change in temperature but the amount of this change, β (coefficient of cubical expansion), varies widely with different liquids, and to some extent for the same liquid at different temperatures. See special table, *Coefficients of Cubical Expansion for Various Liquids and Aqueous Solutions.*

The table below, which is calculated from the relationship:

$$F_{\beta t}=\frac{density\ of\ water\ at\ 25°C.\ (=0.99705)}{[1-\beta\ (25-t)]} \quad (1)$$

may be used to find d^t, the density (weight of 1 cc.), of a liquid at any temperature (t) between 0° and 40°C. if the specific gravity at 25°/25°C. (S) and the coefficient of cubical expansion (β) are known. Substitutions are made in the equations:

$$d^t=SF_{\beta t} \quad (2)$$

$$S=\frac{d^t}{F_{\beta t}} \quad (3)$$

TABLE—FACTORS ($F_{\beta t}$)

Density t°C. = Sp. Gr. 25°/25° × $F_{\beta t}$

°C. / *$\beta \times 10^3$	0	5	10	15	20	25	30	35	40

* β = coefficient of cubical expansion.

EXAMPLES

All examples are based upon an assumed coefficient of cubical expansion, β, of 1.3×10^{-3}.

Example 1. To find the density of a liquid at 20°C., d^{20}, which has a specific gravity (S) of $1.2500^{25°}_{25°}$.

From the table above $F_{\beta t}$ at 20°C. = 1.0036.

$$d^{20}=d^t=SF_{\beta t}=1.2500\times1.0036=1.2545$$

CONVERSIONS OF DENSITY—SPECIFIC GRAVITY

Example 2. To find the density at 20°C. (d^{20}) of a liquid which has a specific gravity of $1.2500^{17.5°}_{4°}$.

Since the density of water at 4°C. is equal to 1, specific gravity at $17°/4° = d^{17} = 1.2500$.

Substitution in equation *3* with $F\beta_t$ at 17°C., by interpolation from the table, equal to 1.00756, gives

$$Sp.\ gr.\ 25°/25° = S = 1.2500 \div 1.00756$$

Substitution of this value for S in equation *2* with $F\beta_t$ at 20°C., from the table, equal to 1.0036, gives

$$d^{20} = d^t = (1.2500 \div 1.00756) \times 1.0036 = 1.2451$$

Example 3. To find the specific gravity at 20°/4°C. of a liquid which has a specific gravity of $1.2500^{25.8°}_{4°}$.

Since the density of water at 4°C. is equal to 1, specific gravity $25°/4° = d^{25} = 1.2500$; and, specific gravity $20°/4° = d^{20}$.

Substitution in equation *3*, with $d^t = 1.2500$; and, with $F\beta_t$ at 25°C., from the table, equal to 0.99705, gives

$$Sp.\ gr.\ 25°/25° = S = 1.2500 \div 0.99705$$

Substitution of this value for S in equation *2*, with $F\beta_t$ at 20°C., from the table, equal to 1.0036, gives

$$Sp.\ gr.\ 20°/4° = d^{20} = (1.2500 \div 0.99705) \times 1.0036 = 1.2582$$

Example 4. To find the density at 25°C. of a liquid which has a specific gravity of $1.2500^{\frac{5}{8}°}_{\frac{5}{8}°}$.

Since the density of water (see special table, *Absolute Density of Water*) at 15°C. = 0.99910,

$$d^{15} = sp.\ gr.\ 15°/15° \times 0.99910 = 1.2500 \times 0.99910$$

Substitution in equation *3*, with $F\beta_t$ at 15°C., from the table, equal to 1.0102, gives

$$Sp.\ gr.\ 25°/25° = S = (1.2500 \times 0.99910) \div 1.0102$$

Substitution of this value for S in equation *2*, with $F\beta_t$ at 25°, from the table, equal to 0.99705, gives

$$d^{25} = d^t = (1.2500 \times 0.99910 \div 1.0102) \times 0.99705 = 1.2326$$

DENSITY OF AQUEOUS SOLUTIONS

The values in the following tables have been computed from the values given under *specific gravity* and *per cent by weight* by means of the following factors:

$$\textbf{Degrees Baumé} = 145 - \frac{145}{\text{Sp. gravity}}$$

Degrees Twaddell = (Sp. gravity -1)$\times 200$
Grams per Liter = Sp. gravity $\times$ per cent by weight $\times$ 10
Pounds per U. S. Gallon = Grams per Liter $\times$ 0.0083454
Pounds per Cubic Foot = Grams per Liter $\times$ 0.06243

See also the tables:—"*Specific Gravity of Aqueous Solutions*", "*Specific Gravity of Alcohol Water Solutions*," and "*Hydrometer Conversion Tables.*"

ACETIC ACID

Density of Aqueous Acetic Acid Solutions at $\frac{20}{4}$° C. Computed from Values Given in the International Critical Tables.

AMMONIA

Specific Gravity of Aqueous Ammonia Solutions.

Adopted 1903 as Standard by the Manufacturing Chemists' Association of the United States.

Authority: W. C. Ferguson.

Specific Gravity determinations were made at 60° F., compared with water at 60°F.

From the Specific Gravities the corresponding degrees Baumé were calculated by the following formula:

$$\text{Baumé} = \frac{140}{\text{Sp. Gr.}} - 130.$$

* Baumé Hydrometers for use with this table must be graduated by the above formula, which formula should always be printed on the scale.

Atomic weights from F. W. Clarke's table of 1901. O = 16.

HYDROCHLORIC ACID

Specific Gravity of Aqueous Hydrochloric Acid Solutions. Adopted 1903 as Standard by the Manufacturing Chemists' Association of the United States.

Authority: W. C. Ferguson.

Specific Gravity determinations were made at 60° F., compared with water at 60°F.

From the Specific Gravities, the corresponding degrees Baumé were calculated by the following formula:

$$\text{Baumé} = 145 - \frac{145}{\text{Sp. Gr.}}$$

* Baumé Hydrometers for use with this table must be graduated by the above formula which formula should always be printed on the scale.

Atomic weights from F. W. Clarke's table of 1901. O = 16.

ALLOWANCE FOR TEMPERATURE:

10 — 15° Be. — 1/40° Be. or .0002 Sp. Gr. for 1° F.
15 — 22° Be. — 1/30° Be. or .0003 Sp. Gr. for 1° F.
22 — 25° Be. — 1/28° Be. or .00035 Sp. Gr. for 1° F.

NITRIC ACID

Specific Gravity of Aqueous Nitric Acid Solutions. Adopted 1903 as Standard by the Manufacturing Chemists' Association of the United States. Authority: W. C. Ferguson.

Specific Gravity determinations were made at 60° F., compared with water at 60° F. From the Specific Gravities, the corresponding degrees Baumé were calculated by the following formula:

$$\text{Baumé} = 145 - \frac{145}{\text{Sp. Gr.}}$$

Baumé Hydrometers for use with this table must be graduated by the above formula, which formula should always be printed on the scale.

Atomic weight from F. W. Clarke's table of 1901. O = 16.

ALLOWANCE FOR TEMPERATURE:

At 10° — 20° Be. — 1/30° Be. or .00029 Sp. Gr. = 1° F.
20° — 30° Be. — 1/23° Be. or .00044 Sp. Gr. = 1° F.
30° — 40° Be. — 1/20° Be. or .00060 Sp. Gr. = 1° F.
40° — 48.5° Be. — 1/17° Be. or .00084 Sp. Gr. = 1° F.

SULFURIC ACID

Specific Gravity of Aqueous Sulfuric Acid Solutions Adopted 1904 as Standard by the Manufacturing Chemists' Association of the United States.

Authorities: W. C. Ferguson; H. P. Talbot.

Specific Gravity determinations were made at 60° F., compared with water at 60°F.

From the Specific Gravities, the corresponding degrees Baumé were calculated by the following formula:

$$\text{Baumé} = 145 - \frac{145}{\text{Sp. Gr.}}$$

SULFURIC ACID (Continued)

Baumé Hydrometers for use with this table must be graduated by the above formula, which formula should always be printed on the scale.

66° Baumé = Sp. Gr. 1.8354.

1 cu. ft. water at 60° F. weighs 62.37 lbs. avoirdupois.

Atomic weights from F. W. Clarke's table of 1901. O = 16.

H_2SO_4 = 100 per cent

	H_2SO_4	O. V.	60°
O. V.	93.19	100.00	119.98
60°	77.67	83.35	100.00
50°	62.18	66.72	80.06

Acids stronger than 66° Bé should have their percentage compositions determined by chemical analysis.

* Calculated from Pickering's results, Journal of London Chemical Society, vol. 57, p. 363.

ZINC CHLORIDE

Specific Gravity of Aqueous Zinc Chloride Solutions Adopted 1922 as Standard by the Manufacturing Chemists' Association of the United States.

Authorities: W. H. Whitney, E. H. Hartle, C. H. Sakryd.

Checked by: L. C. Drefahl, R. M. Meiklejohn, R. O. Fernandez.

Specific gravity determinations were made at 60° F., compared with water at 60° F., on solutions of Zinc Chloride made from chemically pure zinc and Hydrochloric Acid, these solutions exhibiting a neutral reaction to methyl orange when diluted below 5° Bé with water.

The corresponding degrees Baumé were calculated from the Specific Gravities by the following formula:

$$\text{Baumé} = 145 - \frac{145}{\text{Sp. Gr.}}$$

Baumé Hydrometers for use with this table must be graduated by the above formula, which formula should always be printed on the scale.

1 cubic foot of water weighs 62.37 lbs. avoirdupois.

Atomic weights used: F. W. Clarke's table of 1912. O = 16.

*The percentage composition on all fixed points were determined by actual chemical analysis both Zinc and Chlorine being determined.

ETHYL ALCOHOL

Specific gravity of aqueous solutions of ethyl alcohol at $\frac{15.56°}{15.56°}$ C. To convert to specific gravity at $\frac{15.56°}{4°}$ C, multiply the specific gravities as given in the table by 0.99908.

(U. S. Dept. of Agriculture.)

Specific gravity $\frac{15.56°}{15.56°}$C.	% Alcohol by volume	% Alcohol by weight	Grams Alcohol per 100 cc

METHYL ALCOHOL

Specific gravity of aqueous solutions of methyl alcohol at $\frac{15.6°}{15.6°}$ C. To convert to specific gravity at $\frac{15.4°}{4°}$ C, multiply the specific gravities as given in the table by 0.99908.

[Arkiv. Kemi Min. Geol. [2] 27, 32 (Stockholm.)]

IMMERSION REFRACTOMETER READINGS OF METHYL ALCOHOL AND ETHYL ALCOHOL AT 17.5°C.—DETERMINATION OF MIXTURES OF METHYL ALCOHOL AND ETHYL ALCOHOL IN AQUEOUS SOLUTION

The data in the table below are given in the *Official and Tentative Methods of Analysis*, 4th ed. (1935), p. 175; reprinted by permission of the Association of Official Agricultural Chemists, Washington, D. C.

The method for the determination of mixtures of these two alcohols is that of Leach and Lithgoe, *Jour. Amer. Chem. Soc.* 27, 964 (1905) as corrected by Williams, *Ind. Eng. Chem.* 19, 844 (1927).

Example.—To calculate the percentage of methyl and ethyl alcohols in an aqueous mixture, assuming a distillate with an immersion refractometer reading of 35.0 at 17.5°C. and a specific gravity of 0.9793 at 15.56°/15.56°C.

By reference to the table below, an aqueous solution of methyl alcohol of specific gravity 0.9793 at 15.56°/15.56°C. has an immersion reading of 23.2; an aqueous solution of ethyl alcohol of specific gravity 0.9793 at 15.56°/15.56°C. has an immersion reading of 39.4. The difference between these two values is: (39.4 − 23.2), or 16.2; therefore, (39.4 − 35.0) ÷ 16.2, or 27.2% of the alcohols present in the mixture is methyl alcohol.

By reference to tables showing the percentages of these alcohols corresponding to the various specific gravities, an aqueous methyl alcohol solution having a specific gravity of 0.9793 at 15.56°/15.56°C. contains 15.72% by volume of methyl alcohol. An aqueous solution of ethyl alcohol of the same specific gravity contains 16.80% by volume of ethyl alcohol. A distillate of this same specific gravity in which 27.2% of the alcohol is methyl alcohol and 72.8% is ethyl alcohol would contain: 16.80 − [(16.80 − 15.72) ÷ 27.2], or 16.76% by volume of total alcohols. Since 27.2% of this volume is methyl alcohol, 100 cc. of the solution contain 4.56 cc. of methyl alcohol and 12.20 cc. of ethyl alcohol. At 15.56°C., 1 cc. of methyl alcohol weighs 0.7958 g., and 1 cc. of ethyl alcohol weighs 0.7939 g. Therefore, 100 cc. of the distillate contain 4.56 × 0.7958, or 3.63 g. of methyl alcohol; and, 12.20 × 0.7939, or 9.69 g. of ethyl alcohol. As 100 cc. of the distillate weigh 97.93 g., the distillate contains: 3.63 ÷ 97.93, or 3.71% by weight of methyl alcohol; and, 9.69 ÷ 97.93, or 9.89% by weight of ethyl alcohol

This shows that there is present:	By weight	By volume
Methyl alcohol :	3.71%	4.56%
Ethyl alcohol :	9.89%	12.20%

CONVERSION OF PERCENTAGES OF ETHYL ALCOHOL

The following expressions show the various relations between percentage by weight (W), percentage by volume (V), percentage proof spirit (P), and specific gravity (D).

$$W=\frac{P}{D\times 2.208} \qquad V=\frac{W\times D}{0.7938}=W\times D\times 1.26$$

$$W=\frac{V\times 0.7938}{D} \qquad V=P\times 0.5706 \qquad P=\frac{V}{0.5706}=V\times 1.7525$$

$$P=W\times D\times 2.208$$

Pumice	0.37–0.9	23–56
Quicklime	2.3–3.2	143–199
Red lead	8.6–9.1	536–567
Rock salt	2.28–2.41	143–150
Rosin	1.07	66.7
Rubber fabric	1.0–2.0	62.3–125
Rubber, gum	0.92–0.96	57.3–59.8
Rubber, raw	0.92–0.96	57.3–59.8
Rye	0.68–0.79	42.4–49.2
Sand, coarse	1.4–1.5	87–93.5
Sand, fine, dry	1.40–1.65	87.2–102.8
Sand, fine, moist	1.90–2.05	118.4–127.7
Sandstone	2.2–2.5	137–156
Sandstone, artificial	2.0–2.1	125–131
Sea water	1.025	63.86
Siderite	3.7–3.9	231–243
Silica	2.66	166
Silk, raw	1.56	97.2
Slag, blast furnace	2.5–3.0	156–187
Slaked lime	1.15–1.25	69.6–77.9
Slate	2.65–2.70	165–168
Snow, loose	0.125	7.79
Soapstone	2.7	168
Starch, lumps	1.53–1.56	95.3–97.2
Steel, ingot	7.87	490
Sugar, white	1.61	100.3
Tallow	0.90–0.97	56.1–60.4
Tar	1.02	63.6
Tufa, lump	1.3	81
Tufa, tile	0.8–0.9	50–56
Verdigris	1.9	118
Wax, sealing	1.8	112
Wheat	0.7–0.8	44–50
White lead	6.7	417
Wood	0.31–1.33	19.3–82.9
Wood naphtha	0.810–0.848	50.5–52.9
Wool, air dried	1.32	82.2

RELATIVE DENSITY AND VOLUME OF WATER* AND OF MERCURY AT VARIOUS TEMPERATURES

These values are based upon the mass of one milliliter of water at 4°C. as unity. To convert to absolute density in C. G. S. units multiply the value for relative density by 0.999973.

WATER			MERCURY		
Temp. Degree C.	Relative Density g/ml	Volume ml/g	Relative Density g/ml	Volume ml/g	Temp. Degree C.

FREEZING MIXTURES

The table below gives the percent of the anhydrous material as shown in the column on the left in the eutectic mixture with ice. The eutectic temperature is the lowest temperature which can be obtained from a mixture of the substance with ice. To obtain the maximum cooling effect, the freezing mixture should be prepared with ice rather than with water and the other ingredient should be cooled to 0°C. For most purposes sodium chloride and ice, or calcium chloride and ice, mixtures are most common providing temperatures of -21.2°C. and -55°C. respectively.

Formula of Substance	%	Eutectic Temp. °C.
$BaCl_2$	22.5	−7.8
$CaCl_2$	29.8	−55
$Ca(NO_3)_2$	35	−16
$CuCl_2$	36	−40
$Cu(NO_3)_2$	36	−24
$CuSO_4$	11.9	−1.6
$FeCl_3$	33.1	−55
$FeSO_4$	13.04	−1.824
HCl	24.8	−86
HNO_3	32.7	−43
K_2CO_3	39.5	−36.5
KCl	19.75	−11.1
K_2CrO_4	36.6	−11.3
KOH	31.5	−65
KNO_3	10.9	−2.9
$MgCl_2$	21.6	−33.6
$Mg(NO_3)_2$	34.6	−29
$MgSO_4$	19	−3.9

Formula of Substance	%	Eutectic Temp. °C.
$MnSO_4$	32.2	−10.5
NH_4Cl	18.6	−15.8
NH_4NO_3	41.2	−17.35
$(NH_4)_2SO_4$	38.3	−19.05
NaBr	40.3	−28
Na_2CO_3	5.9	−2.1
NaCl	23.3	−21.13
NaOH	19	−28
$NaNO_3$	37	−18.5
Na_2SO_4	12.7	−3.55
$Na_2S_2O_3$	30	−11
$NiSO_4$	20.6	−4.15
SO_3	32	−75
$SrCl_2$	26	−18.7
$Sr(NO_3)_2$	24.5	−5.75
$ZnCl_2$	51	−62
$Zn(NO_3)_2$	39.4	−29
$ZnSO_4$	27.2	−6.55

NON-AQUEOUS COOLING BATHS

Low temperatures may be produced by mixtures of various substances with carbon dioxide snow or by evaporation of low boiling liquids.*

Substance	Deg. C.
Alcohol-carbon dioxide	−72
Ammonia, boiling point	−33.4
Chloroform-carbon dioxide	−77
Ether-carbon dioxide	−100
Ethyl chloride, boiling point	+12.5
Liquid air, boiling point	−190

Substance	Deg. C.
Nitrogen, boiling point	−196
Oxygen, boiling point	−183
Sulfur dioxide, boiling point	−10

* The assertion that certain baths with CO_2 snow, especially the acetone bath, give a temperature materially lower than pure dry CO_2 snow is erroneous. Cf. Thiel and Caspar, *Z. physik. Chem.* **86,** *257–93 (1914); C. A.* **8,** *1229 (1914).* Liquid air poured into ethyl alcohol until a slush is formed gives a cooling bath −115° to −125°C.

MOLECULAR DEPRESSION OF THE FREEZING POINT

The constant K_F gives the depression of the freezing point in °C. produced by solution of one gram molecular weight of a substance in 1000 grams of any one of the solvents listed below.

Compound	Freezing Point °C.	K_F	Heat of Fusion gram-cal. per gram
Acetic acid	16.7	3.9	43.2
Aluminum bromide	97.5	26.8	10.47
Barium chloride	962	108	27.8
Benzene	5.5	5.12	30.1
Benzophenone	48.5	9.8	23.5
Bromoform	7.8	14.4	10.9
Camphor*	178.4	37.7	10.74
Cyclohexane	6.5	20.0	7.4
m-Dinitrobenzene	89.8	10.6	24.7
1, 4-Dioxane	10.5	4.9	.....
Diphenyl	70.0	8.0	28.8
Diphenylamine	52.9	8.6	25.2
Ethylene bromide	9.98	12.5	13.5
Formamide	2	3.8	.....
Formic acid	8.6	2.77	58.9
Naphthalene	80.2	6.9	36.0

Compound	Freezing Point °C.	K_F	Heat of Fusion gram-cal. per gram
β-Naphthol	122.5	11.25	31.3
Nitrobenzene	5.7	8.1	22.46
Phenanthrene	99.3	12.0	25.0
Phenol	42	7.27	29.0
Salol	43	12.3	16.13
Stannic bromide	31	28.0	6.49
Stearic acid	69	4.5	47.6
Strontium chloride	873	107	25.6
Sulfuric acid	10.5	6.81	24.03
p-Toluidine	44.5	5.2	39.9
Tribromophenol	96	20.4	13.4
Triphenyl methane	93	12.45	21.1
Triphenyl phosphate	49.9	11.76	17.56
Urethane	49.7	5.14	40.9
Water	0	1.86	79.67
p-Xylene	13.2	4.3	38.1

*According to Rast (*Ber.* 55, 1051, 3727 (1922)) molecular weight determinations may be made with an ordinary thermometer.

MOLECULAR ELEVATION OF THE BOILING POINT

The constant K_B gives the elevation of the boiling point in °C. produced by solution of one gram molecular weight of a substance in 1000 grams of any one of the solvents listed below. In the column headed *Barometric Correction* is given the number of degrees for each mm. of difference between the barometric reading and 760 mm. of mercury to be subtracted from K_B if the pressure is lower, or added if higher, than 760 mm. Cf. Hoyt and Fink, *J. Phys. Chem.* 41, 453 (1937).

Compound	Boiling Point °C.	K_B	Barometric Correction per mm. Hg	Heat of Vaporization gram-cal. per gram.
Acetic Acid	118.5	3.07	0.0008	96.8
Acetone	56.00	1.71	0.0004	124.5

Water	100.00	0.512	0.0001	539.6

AZEOTROPIC MIXTURES

These tables give the data for various binary and ternary azeotropic or constant boiling mixtures.

For a thorough discussion of Azeotropy, see Lecat, *Traite de Chimie Organique*, V. Grignard, Mason et Cie, Paris, 1935, Tome I, pp. 121 to 267; or Young, *Distillation Principles and Processes*, Macmillan, London, 1922.

The boiling points listed are in °C. at 760 mm.

These data are taken from Lecat, "*L'Azeotropisme*", Brussels, 1918; *Ann. soc. sci. Bruxelles 45B, 169–76, 284–94 (1926)*; *47B, i, 21–7, 63–71, 108–14, 149–58 (1927)*; *48B, i, 13–22, 54–62, 113–26; ii, 1–18 (1928)*; *49B, ii, 17–47, 109–43 (1929)*; *50B, 21–33 (1930)*; *55B, 43–7, 253–65 (1935)*; *56B, 41–54, 221–34 (1936)*; *Rec. trav. chim. Pays-Bas 45, 620–7 (1926)*; *46, 240–7 (1927)*; *47, 13–18 (1928)*, unless otherwise designated as follows:

EQUIVALENT CONDUCTANCE OF THE SEPARATE IONS

Johnston, *Jour. Am. Chem. Soc.*, *31*, *1010* (*1909*).

The equivalent conductivity at infinite dilution of a salt may be obtained by adding the equivalent conductivity of the separate ions as given below. Thus Λ_o for KCl at 18° C. is 64.6 + 65.5 = 130.1.

	Λ_o in $cm^{-1}ohm^{-1}$ / gram equivalents per cm^3							
Ion	0°C.	18°C.	25°C.	50°C.	75°C.	100°C.	128°C.	156°C.

ELECTRICAL CONDUCTIVITY OF AQUEOUS SOLUTIONS

In the table below are given values for the conductivity and the equivalent conductivity of various aqueous solutions. The percent by weight is that of the anhydrous substance. The conductivity in mhos/cm. divided by the conductivity in gram-equivalents per cubic centimeter is the equivalent conductivity.

Formula	Temp. °C.	% by Weight	Cond. mho/cm ×10⁴	Equiv. Cond.

ELECTRICAL CONDUCTIVITY OF STANDARD SOLUTIONS

In the table below, the normal KCl solution was prepared by dissolving 74.59g of KCl in water and diluting to one liter at 18°C. The specific gravity of such a solution is 1.0449 at 18°C.

The concentrations of H_2SO_4 and of $MgSO_4$ are those of maximum conductivity at 18°C.

The NaCl solution is saturated at all the temperatures given, and has a specific gravity of 1.2014 at 18°C.

	Conductivity in mhos/centimeter, or $ohm^{-1}cm^{-1}$.

RELATIVE HUMIDITY TABLES

For Use with Hygrometer

Reprinted by Permission of The Taylor Instrument Companies, Rochester, N. Y.

The following tables are computed from data supplied by the U. S. Bureau of Standards, and are correct at a barometric pressure of 29.92 inches or 760 mm. of mercury. The values above 140° dry-bulb are extrapolated. Complete tables covering barometric pressures may be obtained by applying to the Superintendent of Documents, Government Printing Office, Washington, D. C. for psychrometric tables WB No. 235.

Use of Tables.—Locate at either the top or bottom margin the reading corresponding to the dry-bulb indication. Locate at either side margin the reading corresponding to wet-bulb indication. At the intersection of these two columns can be read the relative humidity. For example—given dry-bulb temperature 144°F. and wet-bulb temperature 112° F., relative humidity is 36%.

Precautions.—When the wick of an hygrometer becomes hard the bulb will not be thoroughly wet and inaccurate readings will result. Care should be taken to keep the wick clean. It should not be handled unless the fingers are perfectly clean, and the water should be pure and soft; distilled water is preferable. If the wick surrounding the bulb becomes hard (which can be easily detected by feeling of it) it should be discarded and replaced by a new one.

Accurate Readings.—Accuracy with fixed position hygrometers can be obtained only by creating free circulation around the bulb. When taking observations, fan the bulb vigorously for a full minute or more, then immediately take the reading.

Use of Sling Psychrometer.—Saturate the wicking covering the bulb with water at room temperature, then whirl the instrument for 15 or 20 seconds, holding it away from the body. Stop and note the indication of wet-bulb thermometer; then repeat the operation until two or more readings agree at the lowest indication obtainable. The wicking must be kept perfectly clean and thoroughly saturated to secure accurate indication.

Humidity Below the Freezing Point.—At temperatures below freezing apply water to the bare wet bulb sparingly, a thin coat of ice will then be formed on the bulb, and evaporation from the frozen surface will go on as before. In the case of desk-type and wall-type hygrometers the capillary effect of the wicking is lost when frozen so that water will have to be applied directly to the bare bulb.

DRY BULB TEMPERATURE °F

WET BULB TEMPERATURE °F

SOLUTIONS FOR MAINTAINING CONSTANT HUMIDITY

A saturated aqueous solution in contact with an excess of a definite solid phase at a given temperature will maintain constant humidity in an enclosed space. The table below gives a number of salts suitable for this purpose listed in order of decreasing humidity. The aqueous tensions were obtained by multiplying the percent humidity by the vapor pressure of pure water (mm. of Hg) at the same temperature.

Solid Phase	Temp. °C.	% Humidity	Aqueous Tension
TlCl	100.097	99.7	760.5
$TlNO_3$	100.317	98.7	758.6
$Pb(NO_3)_2$	20	98	17.2
$CaSO_4 \cdot 5H_2O$	20	98	17.2
NaF	100.0	96.6	734
$Na_2SO_3 \cdot 7H_2O$	20	95	16.7

VAPOR PRESSURES OF VARIOUS SUBSTANCES

The following table gives the values of A and B in the equation: $\log_{10} P_{mm} = \frac{-52.23\,A}{T} + B$, where P_{mm} = vapor pressure of the substance in mm of Hg and where T = absolute temperature = t°C + 273.1. The values obtained by the use of this equation are valid within the temperature ranges indicated for each of the compounds. See also another table "Vapor Pressures of Various Substances" and the table "Orthobaric Densities or Volumes of Various Substances."

Name	Formula	Range, °C.	A	B
Acenaphthene	$C_{12}H_{10}$	147 to 288	54.279	8.033
Acetaldehyde	CH_3CHO	−24.3 to +27.5	27.707	7.8206

VAPOR PRESSURES OF VARIOUS SUBSTANCES

Name	Formula	Range, °C.	A	B
Uranium hexafluoride	UF_6	0 to 69	41.73	9.521
Zinc	Zn	250 to 419.4	133	9.200
		600 to 985	118	8.108

VAPOR PRESSURES OF VARIOUS SUBSTANCES

In the table below, the vapor pressures are given in millimeters of mercury or in atmospheres (1 atmosphere 760 mm Hg) as indicated. Data on some compounds which are not listed in this table may be found in the International Critical Tables, vol. 3, pp 199-246 and in the Landolt-Bornstein Physikalisch-Chemische Tabellen, 5th ed., vol. 2 pp 1332-1381.

The following abbreviations are used: c.p., critical point; t.p., triple point; m.p., melting point.

See also special tables for mercury, ammonia, and water.

VAPOR PRESSURE OF WATER IN MILLIMETERS OF MERCURY

For Temperatures from −10° to 118°C

The values in the table below are for water in contact with its own vapor. Where the water is in contact with air at a temperature t°C, the following correction must be added: Correction for temperatures up to 40°C $= p(0.0775 - 3.13 \times 10^{-4} t)/100$; for temperatures above 50°C $= p(0.0652 - 8.75 \times 10^{-5} t)/100$.

See also Steam Table.

VAPOR PRESSURE OF ICE IN MILLIMETERS OF MERCURY

For Temperatures from −99° to 0°C

The values in the table below are for ice in contact with its own vapor. Where the ice is in contact with air at a temperature t°C, the following correction must be added: Correction $= 20p/100\,(t+273)$.

t°C.	p mm Hg	t°C.	p mm Hg	t°C.	p mm Hg

BOILING POINT OF WATER AT VARIOUS PRESSURES

The table below gives the boiling point of water in degrees Centigrade at various pressures in millimeters of mercury at 0°C.

See also Steam Table.

Pressure	Tenths of a millimeter of Hg									
mm of Hg	0.0	0.1	0.2	0.3	0.4	0.5	0.6	0.7	0.8	0.9

PROPERTIES OF

METRIC AND

The values given in the table below are based upon the values given in Keenan's Steam Tables. (Copyright 1930 by The American Society of Mechanical Engineers, by permission.) The B. T. U. is 778.57 ft.-lb. (= J) which is 1/180 of the change in total heat along the saturated liquid line between 32°F. and 212° F. as determined by Osborne, Fiock and Stimson at the Bu. of Standards. The values given in calories per kilogram have been computed from the values in B. T. U. per pound by means of the conversion factor 0.5556. The heat of vaporization *hfg* is the heat required to vaporize unit mass of water at the indicated temperature and pressure. Total heat

SATURATED STEAM

ENGLISH UNITS

involved is $H=hfg+hf$. The external work is pv and the corresponding amount of heat is Apv where A is 144/778.57. The heat equivalent of internal work is $\rho=hfg-Apv$. The values in kilograms per square centimeter and in millimeters of mercury have been computed from the values in pounds per square inch by means of the conversion factors 0.070307 and 51.715 respectively. The values in cubic meters per kilogram have been computed from the values in cubic feet per pound by means of the factor 0.062428. The densities are the reciprocals of the corresponding specific volumes.

Temperature Degrees Fahrenheit.	Heat equivalent of external work.		Saturated vapor						Temperature Degrees Centigrade.
					Specific volume		Density		
	B.T.U. per pound.	Calories per kilogram.	Entropy of the liquid.	Entropy of vaporization.	Cubic feet per pound.	Cubic meters per kilogram.	Pounds per cubic foot.	Kilograms per cubic meter.

SPECIFIC GRAVITY OF AIR AT VARIOUS TEMPERATURES

The table below gives the weight in grams $\times 10^4$ of one milliliter of air at 760 mm of mercury pressure and at the temperature indicated. Density in grams per milliliter is the same as the specific gravity referred to water at 4°C. as unity. To convert to density referred to air at 70°F. as unity, divide the values below by 12.00.

t°C.	Sp.Gr. $\times 10^4$	t°C.	Sp.Gr. $\times 10^4$	t°C.	Sp.Gr. $\times 10^4$	t°C.	Sp.Gr. $\times 10^4$

HEATS OF SOLUTION

The values given in this table are expressed in kilo-calories per gram mole of compound as shown by the formula and for a dilution as indicated (where this is not indicated the dilution is such that further dilution is without an appreciable, thermal effect); a positive value indicates an evolution of heat during solution. To convert from kilogram calories to B. T. U. multiply by the factor 3.9685.

Name	Formula	Dilution in moles of water	Heat of solution in kg-cal.	Temp. °C.

Zirconyl nitrate	$ZrO(NO_3)_2 \cdot 3\frac{1}{2}H_2O$	....	−1.92	15

VAN DER WAALS' CONSTANTS FOR GASES

Calculated from the values given in *Landolt-Bornstein Phys.-Chem. Tab.*, 5th Ed., p. 254 (1923); published by J. Springer, Berlin.

$$\left(P + \frac{a}{V^2}\right)\left(V - b\right) = RT \text{ for } one \text{ mole}$$

To use the values of a and b in the table below, P must be expressed in atmospheres and V in liters per mole; then $R = 0.08207$ liter atmospheres per mole per degree; T is degrees absolute.

$$\left(P + \frac{n^2a}{V^2}\right)\left(V - nb\right) = nRT \text{ for } n \text{ moles}$$

Name	Formula	a $\frac{(\text{liters})^2 \times \text{atm.}}{(\text{mole})^2}$	b $\frac{\text{liters}}{\text{mole}}$
Acetic acid	CH_3CO_2H	17.59	0.1068

SPECIFIC HEAT OF GASES AND VAPORS

The values of γ in the table below are the ratios of the specific heat at constant pressure (Cp) to that at constant volume (Cv). To convert the values below into joules per gram per degree C., multiply by 4.186.

Gas or Vapor	Temp. °C.	Press. atm.	Specific Heat in cal. 15° per gram per °C. Const. press.	Const. vol.	$\gamma = Cp/Cv$
